

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

THE MECHANICS' MAGAZINE,

AND

JOURNAL OF ENGINEERING, AGRICULTURAL MACHINERY,
MANUFACTURES, AND SHIPBUILDING.

VOL. II.

(NEW SERIES.)

JULY TO DECEMBER, 1859.

EDITED BY

R. A. BROOMAN AND E. J. REED.

"Man is a tool-using animal. Weak in himself, and of small stature, he stands on a basis, at most for the flattest soled, of some half square-foot, insecurely enough; has to straddle out his legs, lest the very wind supplant him. Feeblest of bipeds! Three quintals are a crushing load for him; the steer of the meadow tosses him aloft, like a waste rag. Nevertheless he can use tools, can devise tools: with these the granite mountain melts into light dust before him; he kneads glowing iron, as if it were soft paste; seas are his smooth highway, winds and fire his unwearied steeds. Nowhere do you find him without tools; without tools he is nothing, with tools he is all."—CARLYLE.

"Every structure or machine, whose design evinces the guidance of science, is to be regarded not merely as an instrument for promoting convenience and profit, but as a monument and testimony that those who planned and made it had studied the laws of nature: and this renders it an object of interest and value, how small soever its bulk, how common soever its material. . . . The engineer or mechanic, who plans and works with understanding of the natural laws that regulate the results of his operations, rises to the dignity of a sage."—PROFESSOR RANKINE.

P R E F A C E.

IN placing the Second Volume of our New Series before our readers we avail ourselves of the opportunity which a Preface affords for offering a few remarks that cannot well find a place elsewhere.

We would first express our thanks for the firmness with which men of scientific tastes and pursuits continue to support, in its new form, this Magazine, which other pens than ours made popular many years ago. A thousand things have shown us during the past year that those old friends who long looked upon this journal with even more than a friendly interest, have not had their regards alienated by either the external or the internal changes which it has of late undergone. We have likewise had many proofs of the support which new friends are in various ways according us. By all these manifestations of good feeling we are delighted, and for them we are grateful.

Many subjects of great importance have engaged our attention during the half-year which now expires. Among the earliest of them was that Admiralty Committee on Dockyard Economy, upon which some thousands of pounds of public money were squandered, and which did its best to effect changes involving the squandering of many thousands more. We have good reason to believe that our simple explanations on this subject have left the Committee but little hope of accomplishing its designs. The Coinage of the Realm is another subject that has been discussed with manifest effect in our columns. The manufacture of the new bronze coinage, now in course of preparation, is an acknowledged concession to our representations and efforts. In the present activity of the War Department and the Admiralty in reference to Rifled Ordnance we believe we see a consequence of our urgent remonstrances, followed up as they were by the speeches of that veteran patriot, Lord Lyndhurst, in the House of Peers. The Great Eastern has occupied much of our attention, not altogether, we trust, without effect. It was not possible to speak of her in terms that would be pleasant to all parties, because, as a commercial speculation, she has excited an immense amount of partizanship; moreover, since the memorable explosion which we had the pain of witnessing on her first sea trip, she has been continuously enveloped in a blaze of raging controversy. Happily we have had no interest in her to blind us, and no antipathies to colour what we have seen; so that we have been able to offer unprejudiced and fearless criticisms on this subject, which have not, as we are often assured, been valueless. The abuse of the British Association—by which it was rendered a medium “for advertising inventions” rather than for advancing science—to which we, and we only, drew attention in October last, will in future, we are informed, be guarded against. The Royal Navy, to which we give much attention, and with which we claim a real although humble association, was never in a more prosperous or more efficient condition than it is at present. The movement made by the French in respect of iron-coated ships has been met in a most spirited manner by our Admiralty, and the remonstrances which we publicly made on this subject in May last have been followed by the issue of contracts for no less than *four* iron-defended ships for Her Majesty’s Navy—all of them vessels which promise to be of unparelled power and invulnerability. Our articles on the Theory of Ship-building and Laying-off have been slowly but steadily and carefully proceeded with, and will be continued until they become complete. In reference to Naval Architecture generally we have not been inactive, as is evidenced by the hostility which certain amateur writers on this subject are evincing towards us. The complaint of these gentlemen is, not that we do not understand naval architecture, or that we are devoid of the ability to express ourselves clearly in a literary sense, but that we have too much confidence in ourselves—too little respect for others—for *them* they mean, of course. We can only say we hope this is not so; we shall certainly not believe it is until *competent* judges express the opinion. We will leave this subject by promising to all who are concerned in it—friends and “unfriends”—an interesting novelty, which will come before them, we doubt not, before we pen another preface—a novelty that will gladden the hearts of all true lovers of the noble art of shipbuilding. We must not say more just at present.

But we have said enough in this egotistical strain, and will therefore end here—end with the hope that, notwithstanding the proud burst of new literature with which the year 1860 is opening, our voice will still be waited for with interest, and listened to with attention.

THE EDITORS.

December, 1859.

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, JULY 1, 1859.

OUR COPPER COINAGE.

THE Mint, we learn, is engaged at present in the production of copper coin, of which it is said there exists in many parts of the kingdom a complete dearth. The ebbings and flowings of the copper currency have always been, indeed, perplexing to the authorities of the Mint. There appear to be eddies in the tide of its circulation which are not easily understood, or to be accounted for. Sometimes there is a drifting of pence, halfpence, and farthings to Manchester, then to Glasgow, and next perhaps to Birmingham, or London. Then, again, in particular districts of particular towns, there are strange accumulations and scarcities. For example, there is always a natural current of copper coin towards the East-end of the metropolis. It is more in request—unfortunately for the dwellers therein—in Bethnal-green than in Belgravia, and the supply inevitably follows the demand. A sort of trade wind floats the copper currency through the channels of circulation in this direction, as surely as the literal trade wind wafts commercial argosies across the ocean. These irregularities cannot be avoided, but the Mint is being constantly called upon to correct them, and it can clearly only do so by adding to the quantity of coin in circulation. There are also peculiar businesses which lead to the congregation of copper tokens, and it is a well-known fact that the publican usually pays his brewer's bill with them. It is well to explain these facts perhaps to the public, in order that the whole question of the metallic currency may be comprehended with a view to its ultimate reform. There may be about £800,000 worth of the various denominations of copper coin in existence in Great Britain, and as has been said there is an ever-recurring tendency to an unequal and eccentric distribution of it.

The history of the farthing especially is strange and obscure. It disappears in larger quantities than its bigger brethren and sooner. Yet it has a less active life. It is not popular with a large class of tradesmen. It is beneath their notice, not convenient and unprofitable; hence it is banished from their society. It is an outcast coin only used by pawnbrokers and their victims—we mean customers—chandler's, shopkeepers, and costermongers. In the lowest class of shops in the lowest neighbourhoods, and among the lowliest people only, does the farthing enjoy a brisk circulation. Children hoard farthings, and misers take care of them, but the public generally eschew them. It is with difficulty that the poor farthing, therefore, maintains its ground at all. Possibly, if the sun of England's greatness has not yet reached its zenith, the farthing may some day be swept away in the flood-tide of national prosperity and disappear entirely. At any rate, there is not much prospect of a resuscitation of the half-farthing. This, and the quarter-farthing, and the *oboli*, or tenth of a penny, may be, and are, of use in Ceylon and the Ionian Islands, but they are too small for the notice of the inhabitants of Great Britain, and we trust may ever remain so.

It will be permitted us again to express a hope that in the meditated new bronze coinage we may find an artistically and scientifically perfect substitute for the copper coinage now under doom, and which has been the fruitful source of so much justly severe criticism, and so much practical inconvenience. Whether it may be

possible also to contrive some means of keeping it in equable and healthy circulation, without the evils of local plethora and local famine being experienced, is a question worthy consideration also. Having opened the agitation on the general improvement of the British coinage, it is our intention not to allow it to be closed until that improvement is effected. The importance of the subject does not brook apathy or indifference. It signifies not that Lord Overstone has put his veto on any and every decimal system ventilated before the Commission, whose "final report" on the whole subject of decimal coinage is now printed. There is an admitted—a generally admitted—necessity for a reformation of our inferior metallic currency, and that reformation, of which we see in the forthcoming bronze halfpenny the beginning, must soon be made complete and satisfactory.

NEW SUBMARINE TELEGRAPH
CABLES.

AMONG the many novelties which have lately been introduced as improvements in the construction of submarine telegraph cables there is one which for its extreme simplicity and cheapness appears to deserve the special notice of the public. This is the system of construction which was described in the letter of a correspondent in our last number. In this system the resort to india-rubber as the insulating agent, which has lately found great favour among scientific men, is again renewed, and with it is combined a process of external hardening from which very great advantages may be anticipated. This process appears to have originated in certain practical experiments made by the inventor upon a portion of wire like that of the Atlantic telegraph cable. By an ingenious substitution of a potassium wire for the copper wire the permeability to water of a cable so constructed was made very apparent; but further experiment showed that this permeability was got rid of by the simple expedient of immersing the coated wire in bisulphuret of carbon and chloride of sulphur. The same effect is produced by this process upon india-rubber as well as upon gutta-percha. A further advantage attending the process is, that the "cold vulcanizing," as it is called, at the same time renders the india-rubber or gutta-percha capable of sustaining a heat of no less than 250° Fahrenheit without suffering any injury whatever.

The method of manufacturing the cables upon the improved system is very simple. Successive coatings of india-rubber in a softened state are rolled directly upon the conducting wire by means of powerful pairs of rollers, the pressure of which is sufficient to render the coating substance close and homogeneous. When a sufficient thickness has been laid on in this manner, the cable is passed through the chemical materials before-named, and its surface is thus rendered hard and perfectly non-porous. After this coverings of hemp, wire, gutta-percha, or any other suitable substance may be added if desired to increase the protection of the wire. For many purposes, however, the inventor considers it amply sufficient to incorporate longitudinal fibres of hemp or flax in the outer coating of the india-rubber in order to prevent strain coming upon the conductor, and then to finish the cable with the cold vulcanization.

The inventor of the simple and inexpensive cable is Mr. John Macintosh, of North Bank, Regent's Park, who has had several patents for improvements in submarine cables granted him, and who for twenty years past has had constant experience in the manufacture of india-rubber fabrics. The cost at which he proposes to produce the improved cable is so low in comparison

with the cost of existing cables that shareholders will doubtless receive his offers in this respect with astonishment, while the rapidity with which his machinery works is so great that he undertakes to produce no less than 250 or 300 miles of perfect vulcanized cable per day! The full carrying out of his designs would certainly be an enormous stride in submarine telegraphy, for the apparatus required in the manufacture of the cable is so very simple and compact that he proposes placing it, with a supply of plain india-rubber, on board ship, and then making the cable continuously as it is paid out. This method of proceeding is attended by so little trouble and expense that we can scarcely doubt it will speedily be resorted to in the construction and laying down of many of those numerous cables which the exigencies of commerce and war are now daily demanding.

MR. BESSEMER AND THE IRON
MANUFACTURE.

THREE years ago Mr. Henry Bessemer thought he had accomplished what has very rarely been done in the world—that is, revolutionized a great manufacture by a single discovery—and was mistaken. This year he has really effected what has often before been brought about—that is, improved a great manufacture by laborious and costly experiment. In the paper which was published in the two preceding numbers of this Magazine he has detailed facts which, while important in a commercial sense, also afford valuable lessons to inventors and others.

In adverting to this paper we are struck by the extraordinary want of candour which Mr. Bessemer appears to us to display. In the first place he implies that the paper read by him at the British Association in 1856, was but a step incidental to his pursuit of an inquiry, rather than an announcement of amazing results then already obtained. "The same deep conviction of the truth on which the new process was based, and which led Mr. Bessemer to bring it before the British Association in 1856, has since determined him," we are told, "(in spite of the opinions then pronounced against the process) to pursue one undeviating course until the present time, and to remain silent for years, under the expressed doubts of those who predicted its failure, rather than again bring forward the invention until it had been practically and commercially worked, and there had been produced by it both iron and steel, of a quality which could not be surpassed by any iron or steel made by the tedious and expensive processes now in general use." This representation is not borne out by facts. Every one will remember that Mr. Bessemer spoke at Cheltenham, not of anticipated productions of iron, but of iron which, as was alleged, had actually been manufactured by his new process. In the last paragraph of his paper he distinctly stated this. "In conclusion, allow me to observe," said he, "that the facts which I have had the honour of bringing before the meeting have not been elicited from mere laboratory experiments, but have been the result of working on a scale nearly twice as great as is pursued in our largest ironworks, the experimental apparatus doing 7 cwt. in 30 minutes while the ordinary puddling furnace makes only 4½ cwt. in two hours."

It may suit Mr. Bessemer's present purpose to sink the pretensions which he put forth in 1856; but we cannot forget that the world was then made to believe in a discovery by aid of which iron and steel could at once be produced, without fuel, for the market.

Next we have to expose a further, and equally extraordinary, want of candour manifested in

the allusions which Mr. Bessemer made in his recent lecture to the difficulties which have opposed the successful application of his invention. He says :—

"The want of success which attended some of the early experiments was erroneously attributed by some persons to the "burning" of the metal, and by others to the absence of cinder, and to the crystalline condition of cast metal. It was almost needless to say that neither of the causes assigned had anything to do with the failure of the process in those cases where failure had occurred. Chemical investigation soon pointed out the real source of difficulty. It was found, that although the metal could be wholly decarbonised, and the silicon be removed, the quantity of sulphur and of phosphorus was but little affected; and as different samples were carefully analysed, it was ascertained that red shortness was always produced by sulphur when present to the extent of one-tenth per cent., and that cold shortness resulted from the presence of a like quantity of phosphorus; it, therefore, became necessary to remove those substances. Steam and pure hydrogen gas were tried, with more or less success, in the removal of sulphur, and various fluxes, composed chiefly of silicates of the oxide of iron and manganese, were brought in contact with the fluid metal, during the process, and the quantity of phosphorus was thereby reduced. Thus many months were consumed in laborious and expensive experiments; consecutive steps in advance were made, and many valuable facts were elicited."

Here we are sneeringly told that neither of the causes assigned by disinterested persons for Mr. Bessemer's failures in 1856 had anything to do with those failures; and we are further told that the true cause was the presence of sulphur and phosphorus in the metal produced, the air blast having but little effect upon these impurities. But what are the facts? One of the earliest adverse criticisms of Mr. Bessemer's paper which appeared was an article contributed to the *MECHANICS' MAGAZINE* of September 13, 1856, by Mr. William Truran, the author of an admirable volume on "The Iron Manufacture of Great Britain;" and in that article the author distinctly pointed out the fact that Mr. Bessemer's process did nothing towards the removal of the sulphur and phosphorus from the metal. "Mr. Bessemer committed a great mistake," said Mr. Truran, "when he claimed 'for his plan the production of that quality known as charcoal iron, simply from the refining being conducted without contact with mineral fuel. A superficial acquaintance with the subject would have shown that the quality of the fuel used in the manufacture of a moiety of the bar-iron, so far as regards the usual contaminating ingredients, sulphur and phosphorus, has nothing to do with the ultimate quality of the bar.' And again the same gentleman, in an article which appeared in the *MECHANICS' MAGAZINE* of the following month, said :—"It is questionable if one single atom of phosphorus or sulphur was separated [in Mr. Bessemer's experiments], for the results of analysis are altogether against a more favourable conclusion. Phosphorus and sulphur exist to the extent of 1½ per cent. in many pig-irons, and their removal is essentially necessary to the production of good malleable iron." How Mr. Bessemer could have gone on pottering at chemical analyses in order to discover facts which a sound practical iron-maker was thus clearly placing before him, or how he can now have the effrontery to sneer at those who were taking pains to teach him what he was so manifestly ignorant of, we are at a loss to conceive.

But while we may look to Mr. Bessemer in vain, we fear, for any manly recognition of his own shortcomings, or any grateful acknowledgement of the aid which others offered him, and while we must receive with caution all that he comes forward to say in commendation of his own proceedings, we have no wish to deny that he has at last done good service to the iron ma-

nufacture of the world. The specimens of metal produced by his improved processes which were exhibited at the Institution of Civil Engineers on the evening of his late lecture, and subsequently at the President's conversation, deservedly elicited much praise, and afforded manifest ground for many of the hopeful statements made on the first of these occasions, and published in the abstract lately given in our columns.

It is a most gratifying thing to know that we have now put into our hands a homogeneous malleable metal which may be cast into any desired form, and which leaves the mould free from cracks, flaws, hard veins, &c., and is at the same time of enormous tensile strength. Several samples of the Bessemer steel tested in the proving machine at Woolwich Arsenal bore, according to the reports of Colonel Eardley-Wilmot, R.A., a strain varying from 150,000 lbs. to 162,900 lbs. to the square inch, and four samples of iron boiler plate from 68,314 lbs. to 73,100 lbs.; while according to the published experiments of Mr. Fairbairn, Staffordshire plates bear only a mean strain of 45,000 lbs., and Low Moor and Bowling plates a mean of 57,120 lbs. per square inch. There is also another fact of great importance, as we are reminded, in a commercial point of view. In the manufacture of plates for boilers and for ship-building the cost of production increases considerably with the increase of weight in the plate; for instance, the Low Moor Iron Company demand £22 per ton for plates weighing 2½ cwt. each; but if the weight exceeded 5 cwt. then the price rises from £22 to £37 per ton. Now, with cast ingots such as the one exhibited at the Institution by Mr. Bessemer, and from which the sample plates were made, it was less troublesome, less expensive, and less wasteful of material, to make plates weighing from 10 to 20 cwt. than to produce smaller ones; and, indeed, there was but little doubt that large plates would eventually be made in preference, and that those who wanted small plates would have to cut them from the large ones. A moment's reflection therefore shows the great economy of the new process in this respect; and when it is remembered that every riveted joint in a plate reduces the ultimate strength of each 100 lbs. to 70 lbs., the great value of long plates for girders and for ship-building will be fully appreciated.

Nor can we leave this subject without referring, at the risk of repetition, to the wonderful promises which the Bessemer process holds out to us in reference to the manufacture of ordnance. Many attempts have been made to produce wrought-iron ordnance, and this object has been successfully accomplished in the case the large gun produced at the Mersey forge. But, however perfect this one gun may be, the time required to make it, and its immense cost, manifestly render it still, as Mr. Bessemer stated, a great desideratum to produce guns rapidly and cheaply, of a material equal to, or greater in tensile strength than wrought-iron, and, if possible, free from the liability which that material has to flaws and to deterioration during long exposure to a welding heat. It is believed that the Bessemer process supplies this desideratum, as masses of cast malleable metal can be produced of ten or twenty tons in weight in a single piece, and two or three such pieces may be conveniently made by the same apparatus in one day. The metal so made may be either soft malleable iron, or soft steel. In order to prove the extreme toughness of such iron, and the strain to which it may be subjected without bursting, several cast and hammered cylinders were placed cold under the steam hammer, and crushed without the least tearing of the metal.

These cylinders were drawn from a round cast-iron ingot of only two inches greater diameter than the finished cylinder, and in the precise way in which a gun would be treated; they may, therefore, be considered as short sections of an ordinary 9-pounder field-piece. The tensile strength of the samples, as tested at the Royal Arsenal, was 64,566 lbs. per square inch; while the tensile strength of pieces cut from the Mersey gun gave a mean of 17,550 lbs. longitudinally, and 43,339 lbs. across the grain; thus showing a mean of 17,550 lbs. per square inch in favour of the Bessemer iron. For the accuracy of these figures Mr. Bessemer is responsible. If it is desired to produce ordnance by merely casting the metal, the ordinary founding process may be employed, with the simple difference that the iron, instead of running direct from the melting furnace into the mould must first be run into the converting vessel, where in ten minutes it will become steel or malleable iron, and the casting may then take place in the ordinary manner. Conical masses of this pure tough metal, of from 5 to 10 tons in weight, can be produced at Woolwich at a cost not exceeding £6 12s. per ton, inclusive of the cost of pig iron, carriage, remelting, waste in the process, labour, and engine-power. These important facts have been laid, we are told, before the Government, and their advantages are stated to be fully appreciated by Colonel Eardley-Wilmot, the Superintendent of the Royal Gun Factories, who has evinced a great interest in the progress of the invention from its earliest date.

EXPLOSIONS AT GUNPOWDER WORKS.

It is desirable, we think, before the memory of the late fatal explosions at Hounslow passes entirely from the public mind, to recur once more to certain important considerations suggested by them. In doing this we will, in the first place, revert to the evidence given before the Coroner in reference to the late inquiry, confining ourselves to the last sitting of the jury. The following are extracts from that evidence :—

"Mr. Rowse stated that he was about 90 yards off at the time. It was the lower press exploded first. Could not say whether the treble dust was brought into the press-house over night, or whether more in the morning was taken in a boat; could not say how much there was on the premises the day before. The pressure is taken off by letting the water off directly. The powder was pressed enough. Takes about five minutes to move the powder from the press. Cannot remember how much in the press-house the night before. Might have been fifty barrels. Could not state there was not eight hundred barrels made per week on the premises.

"Mr. Ashby, the manager of the works: Had not any farther information to give as to the cause of the accident. Was now constructing the press in a very different manner with transverse arches, bomb-proof, with 20 feet of earth over. This wall or fence to be between the press-house and the place where the men would work the pumps for the hydraulic pressure. The new press to carry eight barrels instead of double that quantity, as was the case in the late press. There was a Government inspection by two military officers to ascertain the quality of the powder making for Government contracts. The firm had existed 39 years. The mills had been in existence one hundred years. Should not have a water-tank over the new press-house. Considered it caused the great lateral explosion. It was his decided opinion explosions were unavoidable. Had increased the number of mills on the premises by five in the last fifteen years. Had sworn that 400 barrels on an average was the quantity made on the premises at Twickenham per week. Had no reason for subsequent inquiry or other means to alter that statement. Would not swear there was not eight hundred barrels per week made on the premises. In the corning-house, which exploded after the press-house, there were three men employed. The quantity of powder usually there was from ten to fourteen barrels. In the green charge,

or what was now called incorporating houses, forty-two pounds of powder only at a time; forty pounds being allowed by Act of Parliament, and two pounds for waste. In the glazing-house there are about twenty barrels at a time. One-third of the powder glazed at Twickenham works came from the Bedford Mills.

"Henry Atlee: Is a glazing man. Had been much injured. There were one hundred barrels of powder in the glazing-house at the time of explosion; sometimes there are as many as three or four hundred barrels, sometimes only twenty. On the day before the explosion he was in the press-house; saw two hundred barrels there. Forty-nine barrels had been removed from the corning-house to the glazing-house during the morning previous to the explosion. Had no instructions as to quantity of powder to be in the glazing-house at once. Glazed one hundred and thirty barrels a day in both houses. Three men employed. Sometimes glazed more, sometimes less. That was the quantity expected to be done. Worked on Sundays as on other days. Quantity of powder taken into the green charge or incorporating-house was a hundred-weight at a time. Should return to the mills when sufficiently recovered."

We make no reference here to the evidence of Mr. Taylor, the former engineer to the works,—who left, by his own admission, from his "conviction that the several alterations at the "works were of a most dangerous description"—because that evidence, given without solicitation to many persons *ex judicio*, does not appear to us to agree with that rendered by him before the Coroner. We will therefore leave Mr. Taylor out of our future comments, merely reproducing a remark openly made in court, that "Mr. Taylor's evidence would appear to "have been more valuable out of doors than "in." It may appear strange that the important portions of the inquiry, as given above, should differ so widely from the accounts which appeared in most of the daily and other journals. Our notes were, however, taken by an especial hand, and we have great reason to confide in their integrity and truthfulness.

It will have been already observed that while Rowse could not swear there were not 800 barrels made per week, Ashby states there were but 400, but would not say there were not 800, and Atlee gives the quantity glazed as 130 barrels per day—equal, as the work is carried on upon Sunday, to 910 barrels per week! Mr. Ashby further states that the greatest quantity kept in the corning-house was from ten to fourteen barrels. Atlee tells us that forty-nine barrels had been moved to the glazing-house from the corning-house during the morning of the explosion. Mr. Ashby further states that forty-two pounds was the quantity allowed in the incorporating-houses, according to Act of Parliament, and we are left for the moment to infer that the Act has not been treated with contempt. But Atlee steps into the last witness's place, and testifies to the fact that one hundredweight at a time was taken into the incorporating-houses!

Can anything be more lamentable than such a perversion of truth? for either these men are asserting what they know to be contrary to fact, or two out of three of them are apparently ignorant of the most important details of their duties, and consequently totally unfit for the responsible situations they hold. If Atlee is right, what an additional burlesque have we here upon "the solemn commands of "the Legislature." Driving a coach and six through an Act of Parliament is fairly outdone where a hundredweight of gunpowder can so easily blow it to the winds. Will so clear a violation of the law as is here shown be permitted to pass unnoticed by the authorities?

We elicit from the evidence the fact that although there exists no official inspector of gunpowder works, there are two persons deputed to inspect and test the strength of the powder making for the Government. Their

offices must be a sinecure—perhaps placed under some comfortable arrangement which makes "things right"—or we should not have had to allude to the contumely with which a Government Inspector was treated upon demanding admittance at the gates of the works the day after the late accident, and whose person was not even known to the man who had held the post of porter for many years.

Mr. Ashby's statement that the proprietors of the works had determined upon constructing the press in a different manner to carry eight instead of sixteen barrels, is a tacit admission that his own judgment is at variance with that of his employers. We are still disposed to think that even the raising of the mound "upon transverse arches and rendering "it bomb-proof" will not afford sufficient protection for the men, unless the conditions of the Act of Parliament and the *presumed* regulations as to the prescribed quantity of powder to be admitted under the roof at one time be strictly adhered to—bomb-proof not being necessarily gunpowder proof. Mr. Ashby's "decided impression that explosions are unavoidable" we consider a most important and injurious admission, since it partly discredits attempts to mitigate or suppress these calamities; and in the very front of so bold and mischievous an assertion we have lately had in our own columns the testimony of one of the largest firms for the manufacture of gunpowder in the world, where, as a consequence of judicious forethought, and the adoption of "very "many improvements," a fatal accident has not occurred for twenty-five years. This dogged refusal to adopt remedies for the prevention of the sacrifice of "hands"—for such is the conventional term now applied to working men—is not confined to gunpowder works; but happily it does not, through the merciful interference of the Legislature, exist to the same extent as it did a few years ago. Perhaps the Government will ere long see in the manufacture of gunpowder a reason for some change; and as the conditions of one of its Acts has already been grossly violated, it needs no extraordinary excuse for an immediate and searching inquiry.

We have heard it advanced as a *non sequitur* to the suggestion that these mills should be removed further from the presence of large communities, that the communities came to the neighbourhood of the works and not the works to the communities. Now this is partly true and partly false. One set of mills may have existed one hundred years, but we doubt whether the other two sets, some mile or two apart, have been established one-half that time. And in addition to this question of dates—if there really be anything in it—we maintain that it is only within the last few years that by the presence of steam and of huge furnaces, and of the increased number of mills which are admitted to exist by Mr. Ashby, and which several tall shafts of modern construction fully identify, these works have become so formidable and alarming. If, in a word, we are thus far correct, there is not a habitation that has been built fifteen or twenty years, or even less, but what had a *locus standi* prior to the formation of the *bona fide* works as they now exist, and not an inhabitant of such dwellings but what would have a just cause for action if there be any virtue in the old notion of the penalty attached to the formation of a novel nuisance.

THE ROYAL POLYTECHNIC.

It is with the deepest regret we learn the impending close of the above popular Institution. The expenses connected with the accident which

occurred in January last to the spiral staircase has effectually crippled, as we lately intimated, the resources of the directors. The costly litigation of actions on the part of some of the sufferers, and the liberal discharge of a fair and humane consideration of the claims of others, have exhausted the means at the disposal of the directors, and nothing remains but the sale of the premises and their really valuable contents by public auction. This effort having failed, the Institution must be sacrificed, unless another company can be formed to save it from destruction. This, notwithstanding the information which we lately published upon this subject, has not, it now appears, been accomplished. It would be a lasting discredit alike to the scientific taste and moral tone of London if such an Institution should be suffered to cease for want of the few thousand pounds which would at once reinstate it in its position among the unobjectionable and popular Lions of the Metropolis.

On public grounds we venture to press the case of the Polytechnic upon the serious and immediate consideration of public philanthropists. No time is to be lost. A few days will either consign the noble premises to mercantile ends, if not to objectionable purposes still more at variance with the design of the Institution, unless the scientific and religious public interpose their co-operation to restore it to its wonted uses.

THE CASE OF HENRY CORT,

HIS INVENTIONS IN THE MANUFACTURE OF BRITISH IRON.

BY
THOMAS WEBSTER, M.A., F.R.S., &c., Barrister-at-Law.
No. IV.

THE specifications recently published by Mr. Woodcroft, under the authority of the Commissioners of Patents, show that the inventive genius of the country was directed principally, during the first half of the 18th century, to the addition of materials and ingredients, and the adoption of fluxes for facilitating the melting and improving the quality of iron.

In 1728 a patent was granted to John Payne for machinery for obtaining motive power by atmospheric pressure; for improved furnaces and boilers for applying heat; for improvements in the manufacture of iron and salt. The improvements in the manufacture of iron are stated in the specification to consist in putting certain ingredients into fusion with pig and sow iron, viz, the ashes of wood and other vegetables, glass, salt, kelp, and pit-ash cinders from iron furnaces and forges, which ingredients being so put into fusion or melted with pig, sow, or other brittle iron will make the like change as charcoal does in the fire called the finery in common forges, and will render the same into a state of malleability, as to bear the stroke of the hammer, to draw it into bars or other forms at the pleasure of the workman. The specification further states that those or other bars being heated in the said melted ingredients in a long hole, arch, or cavern, are to pass, between two large metal rollers (which have proper notches or furrows upon their surfaces), by the force of the engine thereafter described, or other powers, into such shapes or forms as shall be required. The engine force which was to cause the iron to pass through the rollers, consisted of a large vane wheel hung in a frame in the side of a building, the pressure of the in-current of air being directed upon the extremities of the vanes. It may be presumed to have been a sort of windmill, from which no beneficial result for the purpose proposed could be anticipated. This specification is deserving of notice, as suggesting the use of large metal rollers with notches or furrows on their surfaces

for bringing the iron, drawn by the force of the hammer into bars, into the received shapes and forms; their use would be more analogous to the use of the old slitting rollers, than to the use according to the invention of Cort after the lapse of more than half-a-century.

The furnaces to be employed, as described in Payne's specification, consisted of a series of "arched caverns," from and through which the fiery particles were to be conducted in succession by "fleys" to heat the materials placed therein. From about this time attention would appear to have been directed to caverns as a substitute for the hollow fire and blast in the reduction of the pig or cast into malleable iron, and to the adoption of furnaces closely resembling the reverberatory furnace.

In 1761 a patent was granted to John Wood for a "new way of making malleable iron from pig or sow metal, commonly called cast iron." The conversion, after certain preparatory operations, was to be performed in close vessels in an air furnace, by the aid of certain fluxes which, with the impurities from slag and the iron being brought into a tough and malleable state is wrought into bars under the forge hammer.

In the next year (A.D. 1762) a patent was granted to John Roebuck for "a way of making malleable iron from cast iron." The cast iron was to be melted in a hearth with a blast, and the metal worked until reduced to nature, that is, freed from substances interfering with malleability, then taken out of the fire, separated into pieces, and exposed to the action of a hollow pit-coal fire, heated by the blast of the bellows until reduced to a loop or ball of hot iron, which was to be drawn out under a forge hammer into bar iron. The specification of Roebuck proposes a combination of the hearth with a blast for the melting of the cast iron, and of the hollow pit-coal fire with the blast for the subsequent process of bringing the iron into a mass and state suitable for reduction into bar iron by the action of the forge hammer. The invention of Roebuck has recently been strangely confounded with the puddling process, the invention of Cort more than twenty years afterwards; the former invention was probably intended and may be regarded as an improvement on the well-known blooming process, which was performed by a blast in a hollow fire, whereas Cort's process, known as puddling, is performed without any blast in a reverberatory or air furnace.

This was followed by a patent to John and Charles Wood in the following year (A.D. 1763) for an invention, described in the specification as an improvement on the former patent of John Wood, two years before (A.D. 1761), for "making cast iron malleable without charcoal or blast in an air furnace." The process described is granulation and melting in close pots with a covering of clay, by which the iron becomes perfectly tough and malleable, and is to be wrought under the hammer into half blooms. This was followed by a patent to Thomas and George Crang (A.D. 1766), for "making pig iron malleable in a reverberatory or air furnace with raw pit-coal only." The pig iron is to be put into a reverberatory or air furnace, built of proper construction, and without the addition of anything more than common raw pit-coal, and thereby converted into good malleable iron, and being taken red-hot from the reverberatory furnace to the forge hammer, is to be drawn into bars of various shapes and sizes, according to the will of the workman. The Crangs were in the employ of the Coalbrook Dale Company, then under the management of that eminent man Richard Reynolds, to whom, amongst other things, is due the credit of first employing iron instead of wood in the construction of rail or

tramways between the Severn and different parts of the works. The manufacture of malleable from cast iron with pit-coal had been carried on for upwards of half-a-century* since its introduction in 1713, under the superintendence of Abraham Darby at Coalbrook Dale, and technically termed the "buzzing process," was the last of the series of inventions the subject of letters patent for the conversion of cast into malleable iron by pit-coal, prior to the puddling process of Cort, eighteen years afterwards, towards which, the use of the reverberatory furnace was a step in the right direction.

Patents were granted in 1771 to John Cockshutt, for "making malleable iron directly from the ore in a finery or bloomery," for "refining pig iron with charcoal into wrought iron," and for "a new finery or bloomery," the invention consisting mainly in charging and heating of the finery, and in the greater supply of air to the metal than in the common way. In 1783 (three months after the first of Cort's patents), a patent was granted to Peter Onions, for "working and refining cast iron, and converting the same from a fluid state into wrought or bar iron," by running the cast iron direct from the smelting into another furnace, in which it was subjected to a blast and fire until the metal became less fluid, and thickened into a kind of paste, when it was stirred and again subjected to the blast, the operation of stirring being continued until the scoria separate and the particles of iron cohere, when the workman collects and gathers them into a lump, and after being re-heated to a white heat is taken to the hammer, and forged into malleable iron. The treatment of the iron in this second furnace has been supposed to be a near approach to the puddling of Cort, but they differ in the material particular of the use of a powerful blast as in the ordinary finery, which was a wasteful and extravagant system, whereas in Cort's system no blast whatever was used, but the process was to be completed, as will hereafter appear, without requiring any blast by bellows, or cylinder, or otherwise.

Such appears to be the state of invention and of speculation in this important branch of manufacture prior to and about the time of Cort's inventions; the labours of so many ingenious men, some of whom had opportunities of practising the different processes described in their specifications, must have materially advanced the state of practical knowledge in the manufacture of iron, particularly in the direction to which their labours were mainly directed, namely, the manufacture of bar-iron from pit-coal. The successful employment of pit-coal in the smelting furnace for the manufacture of cast-iron in the preceding century naturally led to its use and substitution for charcoal in the subsequent process of the conversion of cast into bar-iron; this may have been one cause of the reduction in 1740 of the number of furnaces using charcoal or wood fuel, inasmuch as those having only a casual supply would probably be abandoned by reason of the increased use of the pit-coal or mineral fuel, of which the supply was so abundant.

It is not improbable that the estimate given of the number of furnaces in the time of Lord Dudley is too high, and in 1740 is too low, and that allowing for the increased yield of furnaces working continuously with a constant supply of coal over those working intermittently with an uncertain supply, estimated at from 400 or 420

* I am obliged to Mr. Norris for calling attention to an inaccurate statement in the preceding article, to the effect that the manufacture of iron with pit-coal at Coalbrook Dale had been attended with no great commercial success; that process appears to have been carried on continuously from its adoption in 1713.

tons as compared with 60 or 70 tons per annum, the suggested decrease in the quantity of iron made in the country in 1740 as compared with the quantity made in the time of Lord Dudley may not be accurate; calculations made by competent persons on this basis would lead to the conclusion that the quantity must have increased.

However this may be, the quality of the iron was not good; the iron of British manufacture was used only for common purposes, and was not employed in the navy for purposes for which the quality was a material consideration; and in 1784 upwards of 75,000 tons of charcoal bar-iron was supplied from Sweden and Russia for consumption in the naval arsenals and other important works. It is highly probable that specimens of iron of a quality not greatly inferior if not equal to foreign marts were occasionally produced by the skill of British manufacturers working upon some of the suggestions of the many ingenious men who during the preceding century and a half had devoted themselves to a subject of such increasing national importance; the materials, the furnace, the hammers, the rollers, the blowing apparatus were in daily use, but the art whereby iron of a quality suitable for any purpose could be produced with certainty by the manipulation of the unskilled artizan was strictly a mystery; the process whereby such a result was to succeed was not disclosed in any of the specifications referred to, however near previous suggestions and speculations interpreted by the light of successful practice may now appear to have approached thereto. Such have been the characteristics of all progress in every department of knowledge; the fragments, so to speak, of many predecessors are, as it were, gathered up by some fortunate successor and combined into a system which as a whole constitutes, by the common consent of posterity, a landmark in the ocean of speculation, and an epoch in the history of the progress of each particular science. The labours of Henry Cort present such a landmark, and constitute such an epoch in the manufacture of British iron; the practice which he introduced, like the substitution of pit-coal, and the application of the more powerful blast, continues to the present day substantially the same as adopted at the foundry at Fontley, and published to the world in 1783 and 1784 by the specifications of the patents then obtained; the puddling, piling, fagotting, and heating, without the use of the blast and reduction of the iron by rollers, as practiced at Fontley, still survive and form part of the manufacture, whatever additions or alterations may have from time to time been introduced.

MONEY-MAKING AT THE ROYAL MINT.

No. IV.

THE marking-room by its name conveys no sort of explanation of the operations conducted within it. These operations are, nevertheless, of much importance to the artistic finish of the coins to be produced. It contains eight marking machines mounted on strong mahogany frames, and set in motion by straps running over pulleys, and which are in communication with another line of small subterranean shafting, driven by a 20-horse power engine. Shopkeepers and others, for the detection of guilty servants, have, ere now, marked pieces of gold and silver, but the marking pursued at the Mint is, we need not say, for a very different purpose. The "sized,"—or as they might well be named after the judicial ordeal through which they have recently gone, *assized* blanks, are carefully weighed into this room, and then supplied to the attendant markers. A bag containing 720 oz., or 60 lb. troy of the golden pieces is next emptied into a copper pan placed above one of the machines, and a portion of them

are made to fall into, and fill horizontally, or surface upon surface, a couple of feeding tubes. The machine is then started, and straightway the two pieces at the bottom of the tubes are made, by means of a couple of thin sliders, or miniature "shovels," as they are we believe technically called, to advance from beneath the tubes. The pieces are at the same time made to revolve—still in a horizontal position—between two grooved steel cheeks at a requisite distance from each other to administer a considerable amount of pressure to the circumference of the pieces, and, in fact, to raise a rim or protecting edge upon them at the expense of their diameters, which are thus lessened. The marked blanks, after this squeezing, are ejected by the action of the machine itself, and fall forward into a basket lined with pig-skin, and placed to catch them. In the return stroke of the sliders they carry two other pieces from beneath the tubes to the other end of the machine, where a similar amount of pressure is administered to them, and they are deposited in the basket below; this alternate motion is quickly repeated. The attendant has to take especial care that the pieces fall flatly into the tubes, and to keep up a constant supply, whilst a frequent testing of the work, produced by the aid of a steel gauge collar, is necessary also. The pieces must be made of uniform diameter, or as coin presently they would exhibit palpably the irregularity, and then be consigned to the melter, a "consummation" not to be wished at all, much less "devoutly." These machines are rapid in their movements, and 240 blanks per minute are consequently thrown into the basket from each. It must not be supposed that the milling on the edge is given in this way, or at this stage of the process of coining, as many persons imagine. That is, on the contrary, as will be shown, one of the last episodes in the gestative history of the sovereign, and all other milled coins struck at Tower Hill. The marking gives a plain rim only, and the object of this is to render it less necessary to put a very heavy strain on the dies afterwards in the coining press. The protecting edge of the future coin is in fact thus raised, and made ready to receive the *engraving* or beading from the obverse and reverse dies. As soon as one bag of the seeming shankless buttons have been properly "marked," they are returned with the ticket—duly numbered—of their weight to their bag, and are ready for the following process. Of course, in describing the progress of one of these quanta, we have described that of the whole batch of gold of which we have been in pursuit, and it may simplify our subsequent revelations if to that one quantum we confine hereafter our attention. Leaving, then, our friend the marker to his monotonous duty, we follow the bag in question. The officer of the marking, annealing, and stamping branch again verifies, by weighing, the quantity received from the machine, and this time virtually counts them. He divides them into four parcels of 180 ozs. = 15 lbs. troy, or 701 pieces. These parcels are henceforth, when placed in smaller bags, denominated *journies*—from, as formerly explained, the French word *journee*, a day's work—and there is no doubt that in the days of the Norman rule in this kingdom, 701 coins were considered a very good day's work on the part of King William's minters.

The four *journies* of gold are now carefully folded and placed in a butcher's tray, or a vehicle much resembling that dangerous article, and transferred to the annealing-room. Here there are eight ovens, each with an iron door fitted with chains and counterpoise weights; and there are in addition tables plated with iron, small carriages of the latter material, square shallow cast-iron pans with shifting covers, open wrought-iron pans without covers, copper tubes, pot clay, and other paraphernalia for the carrying out of the baking business previously adverted to. The oven then, it may be imagined, is already heated by means of a Jucke's patent furnace, and there is nothing but to supply it with the rich batch to be acted upon. Well, the four *journies* are now once more mixed, and they are placed this time in a mahogany ranging-tray. This has flutings in it, and when shaken the blanks naturally range themselves on their edges in the flutings, and thus render it easy for the worker to take up *rouleaux* after *rouleaux* of them for deposition in the annealing-box. This becomes useful next, and it is of just sufficient dimensions to receive on their edges, and comfortably—that is, without pressing them into it—the 2,804 will-be sovereigns. If this rectangular box were too small, the expansion of the gold pieces by heating would inevitably cause it to fly assunder. Therefore it is that room must be given to allow for their increased bulk. The 2,804 hard pieces of gold—become hard by compression in the laminating and drawing operations—safely ensconced in their box, are covered with thick wrought-iron tops, "to make assurance doubly sure" that no air shall oxidize their surfaces, nor cause volatilization, and with pot clay the joints are plastered over. A carriage mounted on small wheels is in waiting at the oven's mouth to receive the rich freight; it does receive it speedily by use of block and fall, and then the whole is backed into the oven, forming thus a more expensive pie than poor Soyer or Mrs. Smith ever dreamt of. One hour suffices for the cooking; the box and its contents are brought to a cherry-red heat, allowed for a short time—a few minutes—to remain so, and then withdrawn. The box, removed from its carriage (which awaits, and speedily receives another pie) is placed upon the stone floor to cool. While waiting for its cooling, our readers may be told that in the case of silver being operated upon in this department, the open pans or boxes are used, that metal requiring a different mode of treatment, and the time for annealing it being much shorter than that for gold. As regards copper, *that* is baked in copper cylindrical boxes, made air-tight, brought to a red heat, and plunged immediately into cold water. In each case the metal is softened sufficiently for coining. It is now time, however, to remove the crust of our pie. The lids of the box are accordingly taken off, and it is inverted over a copper dish or tray, which receives the contents. A workman catches this up, carries it to a cistern, and transfers the golden discs to a cullender resting beneath a water-tap. A forcible douché bath is now administered to them, and they are thus freed from all foreign matter. But another process awaits them—they must be also *pickled*; for although fire and water have done much to purify them externally, they are not yet sufficiently bright to become honoured with the impress of majesty. A cast-iron copper—if we may be permitted to use an Irishism—lined with lead, and containing a boiling but weak solution of sulphuric acid, awaits in the blanching-room the coming of the candidates for sovereignty. They are speedily deposited therein, and a workman by aid of an ashen pole stirs them so that each individual blank is brought to face the acid. This pickling affair is the work of a few minutes only in the case of gold and silver, which latter requires a stronger solution of sulphuric acid than its richer neighbour; whilst plebeian copper-blanks demand some hours of rest in a cold mixture of acid and water. A number of pickling troughs are therefore provided for the indulgence of the last-named.

The pickled blanks of gold are now removed in the cullender, and again a douché bath of water is given them. By this time a change has come over the spirit of their dream. No longer dull and spiritless pieces of very suspicious-looking metal, they appear in their true colours—bright and beautiful. The most sceptical would not now doubt their being gold—the brass buttons have apparently been doubly gilt while in the copper. They are, however, very wet after their repeated baths, whilst it is necessary that, for stamping, they should be perfectly dry. Provision has been made for this difficulty. In the next apartment, the drying-room, is a drying stove, a cast-iron open bed, about seven feet in length and four in width—at a guess—resting upon brickwork, and having a fire and flue beneath it. This is covered with beech-wood sawdust—found to answer the purpose best—and has upon it sieves and other such like

appliances. Into one of these sieves our friends are placed when removed from the bath, and by friction with the heated sawdust, the workman in charge of the stove soon gets rid of the moisture upon their faces. He is not, however, satisfied with this. There may be particles of dust adhering to them, and these must be got rid of. He has at hand a muffle—a kind of coffee roasting apparatus made of copper, perforated with small holes, and which can be made to revolve within a hollow heated cylinder of iron. Into this "muffle" he next places the smooth and healthy-looking pieces, and here their "drying-out" is soon made complete. Again the officer receives them at the scales, divides the 2804 into the four packets of 701—the journey weight notes on the ticket the working loss in the various operations, if any there haply be—has them replaced in the butcher's tray, and despatches them to the room in which they are to receive finally the stamp of approbation—the portrait and the superscription of our gracious Queen—and to become sovereigns themselves. Silver and copper blanks undergo processes after pickling analogous to those described, the silver becoming in appearance "frosted," and the copper of a bright salmon colour. Six workmen perform the whole of the duties of the marking, annealing, blanching, and drying-rooms.

We have thus seen that as there is a difficulty in making money outside the Mint, so is there some trouble in money-making within that well-guarded establishment. As a lady is said once to have remarked to an officer who had conducted her through its various departments, "Well! if it gives so much trouble to *make* a sovereign, I'm sure we ought not carelessly to spend it." The gold with which we set out from the refinery of Messrs. Brown and Wingrove has now been cast into bars, laminated, drawn, cut, weighed or *assized*—to coin a new word—marked, annealed or baked, pickled, bathed, and dried out for stamping, and in this stage of progress space warns us that till next week we must leave it. It is hoped, moreover, that thus far, at least, our readers have tracked us in our march through the Mint, and gathered much novel information from our teachings.

THEORY OF NAVAL ARCHITECTURE.

No. VIII.

CONTINUING our explanation of the table given in our last article, page 289, last vol., we observe that after the ordinates have been inserted in their respective compartments, the table may be looked upon as a map on which the elevation of the surface is registered from a fixed level.* We now come to the calculations, and in the first place we will obtain the displacement by "vertical sections." Every ordinate is first multiplied by the number standing at the head of its respective vertical column, thus: all ordinates in the first column, headed keel or 5 W. L., is multiplied by $\frac{1}{4}$, those in the second column headed $4\frac{1}{4}$ W. L. is multiplied by 2, and so on for the others.

Let these multiplications be performed for all the vertical columns, and the results inserted immediately under the respective ordinates, as shown in the table in large figures; in practice these results are written in red ink, by which means they are very readily distinguished from the ordinates. This being performed throughout the columns, we readily see that if we add together the results in each horizontal column, the sum when multiplied by one-third of the interval between the horizontal sections will give the semi-area of the corresponding transverse section. For example, in transverse section 8 the sum of .05, 5.8, 5.7, 15.4, 13.5, 39.6, and 10.0, equal to 90.05, multiplied by $\frac{1}{3}$ of 1.5, the common interval, or .5, gives 45.025 for the semi-area of that section.

These sums of the results of the ordinates multiplied by their respective numbers in each

* The figures in the horizontal columns give respectively the ordinates for the transverse sections; and those in the vertical columns the ordinates for the horizontal sections.

horizontal column are placed to the right in the vertical column headed "areas." We must, however, bear in mind that these quantities are not the semi-areas of the several transverse sections; in the present example they are numerically the same as the complete areas of those sections, in consequence of one-third of the distance between the horizontal sections being $\frac{1}{3}$; for multiplying by this fraction, the result is one-half the area of the section, and then multiplying by 2 for both sides gives the same number as is found in the column.

To obtain the displacement from the column headed "areas," these areas, or areas divided by a constant number, might, as we have before stated, be represented by the ordinates of a curve, the line of abscissæ being the middle line of the half-breadth plan, and the ordinates placed at the respective transverse sections, the areas of which they represent.

The area of the figure thus formed will represent the displacement divided by the constant number, one-third of the distance between the horizontal sections. The quantities in this column must, therefore, be multiplied by the numbers for finding the area by the common rule, standing opposite to them respectively in the second vertical column, and the results placed opposite to them in the adjacent column headed "Multiples of areas." The sum of all these numbers, in the present case, equal to 1832.0, when multiplied by $\frac{1}{3}$ of the interval between the horizontal sections, or .5, and then by 4.2, one-third the interval between their vertical sections, giving for a result 3847.2, will be the semi-displacement of the ship in cubic feet.

This multiplied by 2 for both sides gives 7694.4, the displacement in cubic feet for both sides from the L. W. line to upper part of the keel. Were there any portions of the ship outside the extreme sections, these should be calculated by the ordinary rules of mensuration, and added to the above result to give the total displacement. In the present example the only portions situated outside of the extreme sections, are the thin iron keel and the rudder and post, all of which may be safely neglected as inappreciable. The cubic feet divided by 35—the number of cubic feet of sea water in one ton—gives 219.84 as the total displacement in tons to the load water-line.

To obtain the displacement by "horizontal sections," the ordinates in each horizontal column are multiplied by the number opposite to it in the second vertical column from the left; and the results placed immediately to the right of the ordinates, written in red ink, and as is shown in the table in large figures.

Thus:—The ordinates in the horizontal column 1 are multiplied by $\frac{1}{4}$, those in column $1\frac{1}{2}$ by 2; and so forth for all the horizontal columns.

When these are completed, the results will form a series of vertical columns; and it will be seen that the ordinates corresponding to any horizontal section, will have been multiplied respectively by the numbers opposite to them in the second vertical column from the left; the sum, therefore, of the results in the vertical columns, when multiplied by one-third the interval between the vertical sections, give respectively the semi-area of the corresponding horizontal sections. Thus, the sum of these quantities in the vertical column headed L. W. L., or the sum of .05, 1.8, 1.9, 5.8, 6.0, &c., 3.8, 4.0, and .05, altogether equal to 236.95, when multiplied by 4.2 will give the semi area of the load water-section.

These sums for the several horizontal sections, inserted at the foot of the respective columns, are 3.6, 55.2, 103.95, 141.5, 171.4, 209.7, and 236.95, and to proceed as before, instead of multiplying each of these quantities by 4.2 to obtain the semi-area of the sections, we shall regard them as the ordinates of a curve, the line of abscissæ of which is the middle line of the body plan, and the positions of these ordinates, the intersections of this line by the horizontal sections.

These quantities must, therefore, be multiplied by the numbers standing at the head of the vertical columns, viz., by $\frac{1}{4}$, 2, 1, 2, $1\frac{1}{2}$, 4, and 1

respectively, and the sum of the results, 1832.0, carried to the left side of the table, will, when multiplied by 4.2 and .5, give the displacement in cubic feet for one side of the ship.

The quantity 1832.0 is the same as that obtained for the sum of the quantities in the vertical column headed "Multiples of Areas." This shows that the displacement found by obtaining the areas of the horizontal sections, regarding them as ordinates to a curve which forms the boundary of an area representing the displacement, is the same as that found by obtaining the areas of the vertical sections, regarding these as ordinates to a curve which forms the boundary of an area also representing the displacement.

The two results should therefore in all cases be identical, or the calculations are incorrect.

We have now explained all that is necessary to obtain the displacement of a ship to the load water-line. Ships, however, very rarely swim at the constructed load water-line, and their draught of water is constantly altering by the consumption and replenishing of stores, in addition to that variation which arises from alterations, such as in the equipment for a man-of-war, and in cargo for a merchant ship; it is, therefore, necessary to find the approximate displacement for all draughts of water. This is done by means of a scale of displacement formed in the following manner:—The displacements to the several horizontal sections are found by methods already given, and which will be described; a line is then drawn, and a point in it taken to represent the under side of the keel of the ship; from this point are set off according to scale the heights of the several horizontal sections above the under side of the keel; at these heights lines are drawn perpendicular to that line; these lines are then taken to represent tons, and their lengths are proportionate to the number of tons displacement to the respective horizontal sections; a fair curve is then drawn through their extremities, from which the displacement may be very accurately found for any draught of water when the plane of flotation is parallel to the constructed load water-line. In order, however, to find the displacement to the $4\frac{1}{2}$ W. L. it will be necessary to deduce a rule for finding a portion only of the curvilinear area $P_1 P_3 N_3 N_1$ when there are three equidistant ordinates (Fig. 15).

FIG. 15.

In our investigations on page 104 we obtained by the summation of a large number ($2n$) of very small trapeziums, the area of the entire figure between $P_1 N_1$ and $P_3 N_3$; but it is clear that we could have obtained any portion of it, such as that between the ordinates $P_1 N_1$ and $P_2 N_2$.

In this case we should have n trapeziums to sum, instead of $2n$ as before taken.

Referring to page 104 we find that the sum of the n trapeziums will be equal to

$$\begin{aligned} & A \left\{ \frac{m}{n} + \frac{m}{n} + \frac{m}{n} + \&c. \text{ to } n \text{ terms} \right\} \\ & + \frac{Bm^2}{2n^2} \left\{ 1 + 3 + 5 + 7 + \&c. \text{ to } n \text{ terms} \right\} \\ & + \frac{Cm^3}{n^3} \left\{ 1^2 + 2^2 + 3^2 + \&c. \dots + n^2 \right\} - \frac{n^2}{2} \\ & = A \times m + \frac{Bm^2}{2} + \frac{Cm^3}{3} \left\{ 1 + \frac{1}{2n^2} \right\}; \end{aligned}$$

for all values of n , and when n is infinitely large, it is equal to

$$Am + \frac{Bm^2}{2} + \frac{Cm^3}{3}, \text{ since } \frac{1}{2n^2} = \text{Zero.}$$

Putting for A , B , and C their values, as given by the equations on page 104, the sum becomes

$$\begin{aligned} & ma_1 + \frac{m}{4} (4a_2 - a_3 - 3a_1) + \frac{m}{6} (a_3 - 2a_2 + a_1) \\ & = \frac{m}{12} \{ 12a_1 + 12a_2 - 3a_3 - 9a_1 + 2a_3 - 4a_2 + 2a_1 \} \\ & = \frac{m}{12} \{ 5a_1 + 8a_2 - a_3 \}; \end{aligned}$$

which is the area of the part between $P_1 N_1$ and $P_2 N_2$, (shaded in the figure).

To find the area of the portion contained between the ordinates $P_2 N_2$ and $P_3 N_3$; we have only to write a_2 for a_1 in the above equation and it becomes

$$\frac{m}{12} \{ 5a_2 + 8a_3 - a_1 \}.$$

The sum of these two portions, that is, the entire curvilinear area is equal to

$$\begin{aligned} & \frac{m}{12} \{ 4a_1 + 16a_2 + 4a_3 \} \\ & = \frac{m}{3} \{ a_1 + 4a_2 + a_3 \}; \end{aligned}$$

which is the second rule.

Rule.—To find the curvilinear area between two equidistant ordinates, such as of the shaded portion of Fig. 15, in terms of three consecutive equidistant ordinates. Multiply the outside ordinate adjacent to the shaded portion of the figure by 5, and the middle ordinate by 8, add the results together, and subtract the other extreme ordinate from the sum; the remainder multiplied by one-twelfth of the distance between the ordinates, will give the area required.

We have already shown that the quantities 3.6, 55.2, 103.95, 141.5, 171.4, 209.7, and 236.95, or the sums of the vertical columns of large figures in the table page 299, are the areas of the several horizontal sections divided by ascertain number; in order, therefore, to find the displacement to the $4\frac{1}{2}$ W. L. we have only to multiply 3.6 by 5, 55.2 by 8, the sum of which is 459.6, and subtract 103.95 from it, leaving 355.65 as a remainder; this quantity multiplied by one-twelfth of the distance (1.5 ft.) between the horizontal sections, and one-third the distance between the vertical sections, gives 186.7162 for the displacement in cubic feet to the $4\frac{1}{2}$ W. L., and the corresponding number of tons is 5.3347. To obtain the displacement to the 4 W. L., 3.6, 55.2, and 103.95 are regarded as the ordinates to a curve, and multiplied by $\frac{1}{4}$, 2, and $\frac{1}{2}$ respectively, and then multiplying by the proper proportion of the distances between the horizontal and vertical sections, the displacement in cubic feet is found to be 689.635, and in tons 19.701. The whole of which calculations will be readily made out from the table. In obtaining the displacement to the $3\frac{1}{2}$ W. L. the ordinates 3.6, 55.2, 103.95, and 141.5, are multiplied by 1, 3, 8, and 1 respectively, in accordance with the third rule for finding a curvilinear area; the sum of which results or 622.55 when multiplied by the proper proportions of the distance between the horizontal and vertical sections, will give 1470.7748 for the number of cubic feet displacement to that line equal to 42.0221 tons.

To find the displacement to the 3rd W. L. The displacement between the L. W. L. and 3 W. L. is found by multiplying 236.95 by 1, 209.7 by 4, and 171.4 by 1, and adding the results together, giving 1247.15; then multiplying in the usual manner, there results 5238.03, which is the number of cubic feet displacement between the L. W. L. and the 3 W. L., and the number of tons in the same is 149.658; this number subtracted from the total displacement, 219.84, leaves 70.183 for the displacement to the 3 W. L.

The same result would be obtained by making the quantities 3.6, 55.2, 103.95, 141.5, and 171.4, the five equidistant ordinates of a curve, and finding the curvilinear area in the usual way.

The displacement between the L. W. L. and the 2 W. L. is obtained in the same way as that between the upper part of keel and the $4\frac{1}{2}$ W. L.—viz., by multiplying 236.95 by 5, 209.7 by 8, add-

ing the results together giving 2862.35, and subtracting therefrom 171.4, thence leaving 2690.95 for a remainder. This quantity, multiplied by one-twelfth of the distance between the horizontal sections, and then by the constant number 2×4.2 before mentioned, will give 2825.4975 cubic feet, or 80.7285 tons for the displacement between these lines; and, therefore, the displacement to the 2 W.L. is equal to 219.84 — 80.7285 or 139.1115 tons.

To form the scale of displacement, a vertical line, as L.W.L., 5 W.L., drawn on page 298, is taken as the axis of abscissæ, and the dotted line perpendicular to it, marked "lower part of keel," as the other axis of co-ordinates. From the point where these axes intersect the heights of the horizontal sections, above the under side of the keel amidships, are set up according to scale; through the points 4½ W.L., 4 W.L., &c., thus obtained, lines are drawn parallel to the dotted line, and from the vertical line distances are set off upon them, proportionate to the displacement in tons to the corresponding water-line. The scale in the figure is ¼ of an inch to 10 tons; consequently, the distance from the vertical line to the point in the curve at L.W.L. is 21.984 feet on the "quarter" scale. The distance on the horizontal line at 2 W.L. to the point in the curve is 13.91115 feet; and so on for the others.

The very small displacement below 5 W.L. has been neglected in our calculations; consequently, the curve must meet the vertical line at 5 W.L.

When the curve (A) has been drawn through the points thus found, the displacement corresponding to any water-line between 5 W.L. and L.W.L. may be readily found. Thus:—From the dotted line set up a distance equal to the draught of water on the proper scale; and through the point found draw a level line cutting the curve A. The distance of their intersection from the vertical line when set off on the scale of tons will give the displacement required.

THE SEWING MACHINE.

A SKETCH OF THE HISTORY OF ITS INVENTION.

THE essential parts of a sewing machine are but few. Machinery is needed only to pass a thread through the fabric, to retain this thread in the fabric after it has been passed through it, to change the relative position of the fabric and the needle for the formation of the stitches, and to tighten the thread in the fabric so as to form a seam. Every combination of machinery which effects these objects is a sewing machine.

There are five varieties of sewing machines: 1st. Embroidering, tambour, or chain-stitch machines. 2nd. Running-stitch machines. 3rd. Compound chain-stitch machines. 4th. Lock-stitch machines. 5th. Back-stitch machines.

In England, the first inventors of these varieties of the sewing machines, and the dates of their inventions, are as follows:—A tambouring, or chain-stitching machine, was first patented by John Duncan, May 30, 1804. A running-stitch machine was first patented by Leonard Bostwick, April 2, 1844. A machine for making a compound chain-stitch, and also a lock-stitch machine, were first patented by John Fisher and James Gibbons, December 7, 1844. The first patent for a back-stitch machine was granted to Frederick F. Robinson, February 7, 1851. Bostwick's machine is extremely simple, and Robinson's is extremely complicated; but as neither has been used to any considerable extent in this country, they deserve to be named only to make the list of varieties complete. John Duncan and John Fisher are the original inventors of the sewing machines used at present in Great Britain. All other patentees have merely improved upon their inventions.

On the Continent several of these varieties were used before they were patented in England. In France tambouring machines were used about the beginning of the present century. A number of the *London Monthly Magazine*, published in 1817, contains an allusion to an Austrian sewing machine, which may be quoted, as a literary curiosity:—"A Tyrolian has lately invented, at

Vienna, a machine for needlework, by which, it is said, every kind of sewing may be executed with the utmost precision. The Emperor of Austria has granted a patent to the inventor. Should these mechanical perfections make much farther advancement, every thing in the world will shortly be executed by machine."

To Americans, however, the world is indebted for the invention of sewing machines adapted to common use in tailoring, shirt-making, dress-making, boot-making, and similar trades. The high prices paid for common hand-sewing in the United States naturally led to the invention and use of labour-saving machines adapted to plain sewing, just as the high prices of fancy articles for clothing had previously led to the introduction of similar machines among the lace-makers and embroiderers of England. The American inventors who are best known in the United States and in Europe, are Elias Howe, jun., and Sherburne C. Blodgett. The only American manufacturer who is known also as an inventor is J. M. Singer. Elias Howe, jun., has for the past ten or twelve years occupied the first place among the inventors of sewing machines. His patent of September 10, 1846, for the combination of the needle and the shuttle has been generally acknowledged to be at the foundation of the sewing machine trade in the United States. All the leading manufacturers have accepted licences from him, and his income from the royalties thus received is said to amount to not less £20,000 annually. Sherburne C. Blodgett is best known in Great Britain from the fact of his machine being the only one to which a prize was awarded at the Exhibition of 1851. In consequence of this exhibition of sewing machines in London in 1851, and of their exhibition subsequently in Dublin in the following year, the American idea of sewing by machinery became current and popular in this country. Very soon a demand was created for machines superior to those which had previously been used in embroidering and stay-making, and improved machines were rapidly introduced, most of them, however, being of American invention and manufacture. The demand for army clothing during the Crimean war stimulated manufacturers and importers, and the improvements which were being constantly made upon them has tended to increase their usefulness and their sale. In mechanical construction they are rapidly approaching perfection; but it is much to be regretted that the machines sold in England had not been so far reduced in price as to bring them within the reach of the middling classes, and especially of families in moderate circumstances.

FISH-TAIL PROPELLERS.

THE following interesting letter is from the pen of Captain Selwyn, R.N.:—

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN.—I have read with much interest your account of Mr. Reddie's paper read at the U. S. Inst., May 30, and you will perhaps allow me a few remarks on the subject.

Mr. Reddie is scarcely correct in assuming that the "fish-tail" form of propeller has been so much overlooked. It is mentioned in Appendix D, of the new edition of Tredgold's work, and indeed few seamen who give their attention to such subjects have failed to observe and appreciate the admirable ease with which the ocean fishes, propelled only by this means, are able to pass the most rapid steamer when urged to her highest speed. My own thoughts have often been given to the subject; but the difficulty to be met is, or I may say, I think, *was this*, that no backward motion, no "going astern," so essential to steamers, could be obtained from such a form of propeller.

I now see reason to believe, however, that this apparently insuperable difficulty only arose from our not having studied nature quite closely enough. In all those fishes (and there are many) which are capable of rapid backing or stern motion, the breast fins or paddles are used for this purpose, and there seems no reason why we should not avail ourselves of the backing powers of the

screw, combining with it the high velocity of forward motion to be obtained from the use of the fish-tail at the same time astern of the rudder. It is well known that one defect of the screw is, that it does not, under all circumstances, *e. g.*, head to wind, utilize sufficiently the steam power which might be applied to it if there were more perfect resistance. This, any greater area brought to bear on the resisting medium, would effectually absorb; but no advance with the screw alone, in this direction, is possible without at the same time increasing the draught of water. I will give a brief description of the mode of construction and appliance of a "fish-tail" propeller, according to this view. The propeller should first be framed with a central boss, and with hammered brass springs exactly like the bones of a fish's tail projecting from it above and below. Then this framework should be covered with india-rubber, to complete the imitation. The motion might be obtained from the end of the screw shaft by an eccentric, working in a frame which would give

reciprocating horizontal, with any vertical motion from the combined circular motion of the shaft, and this would admit of a joint which is of course necessary being placed in the false stern post or rudder, as most advisable. The rudder would be cut through and jointed, as in the case of those screws which now work astern of the rudder, and which are not uncommon. To provide for the cessation of motion in the fish-tail when going astern, it would be necessary to give a certain degree of "fore and aft" play to the eccentric on the screw shaft, so that the back pull should disengage the eccentric from its frame.

This is, of course, only a rough idea and sketch of what I believe might be done; but it is clear that if practicable, the speed may be greatly increased of all screw vessels, and perhaps also a more efficient power be obtained of steering straight astern.

J. H. SELWYN.

W. Crag, Grasmere, June 15, 1859.

THE EXPERIMENTAL SCREW PROPELLER.

THE annexed figure is an authentic representation of the shape to which the propeller was reduced by cutting off its leading corner in the late experiments made with the *Doris*. It will be perceived that by thus cutting in a straight line, instead of rounding off the corner, two other corners are formed, and the cut being across the thickness of the metal in the blade, a blunt surface was left, which consequently met with greater resistance from the water than it would if chamfered to an edge. That a blade of this im-

perfect shape, with so thick a square edge, should have proved its merits sufficiently to stand second in the order of merit of the propellers tried on that occasion would seem to amount to a proof that a blade formed, as Sir Howard Douglas proposed, in a fair flowing curve throughout, with the leading edge made fine, would be still more successful.

BUNNETT'S PATENT SELF-SUPPORTING FIRE-PROOF FLOORS, ROOFS, AND ARCHES.

BUNNETT'S PATENT SELF-SUPPORTING FIRE-PROOF FLOORS, ROOFS, & ARCHES.

By W. BADDELEY, C.E.

THE recent disastrous conflagration of an oil and turpentine warehouse in Lime-street has caused considerable excitement among the citizens, and led to an inquiry as to the best method of preventing a recurrence of such a disaster. Two things appear to be plainly demonstrated by this fatal occurrence, viz., that large depositories of such highly-inflammable materials ought not to be tolerated in such densely-crowded localities; and that all warehouses for containing such stores, wherever located, should be of fire-proof construction.

Had the building where this unfortunate but purely accidental calamity took place been composed of incombustible materials, with such well-known adjuncts as science furnishes for the purpose, it is almost certain that the contents of one floor only would have been consumed, without any damage to the surrounding properties. As it was, the vast amount of combustible matter employed in the construction of the building literally added "fuel to the fire," increasing the fury of the flames and extending their ravages in all directions around.

Although it is admitted that it is almost practically impossible to construct an absolutely fire-proof building, still much may be done by a judicious disposition of even combustible materials,* to retard the progress of fire and give time

for the application of remedial measures. Many plans have been devised for the construction of fire-proof houses within the last half century, and of these, the last appears to be the most practical. I allude to the methods of constructing self-supporting fire-proof floors, roofs, and arches, recently patented by Mr. Bunnett, the well-known builder's engineer, of Deptford. This invention was briefly noticed in the annual report of London fires for 1858 (ante page 206), and as it is now exciting much interest in the building world, the following additional particulars may probably be interesting to your numerous readers.

Bunnett's fire-proof floors are constructed of hollow or cellular bricks, so formed, externally, as to lock into each other on all sides, so that, when laid to break joints, each brick receives the direct support of six adjoining ones, carrying out a principle of mutual support over the whole extent of the floor.

Figures 1 and 2 show a transverse and longitudinal section of one of these cellular bricks made of clay or brick earth; they are produced by forcing the plastic clay through dies or moulding orifices, the dies being so formed as to cause each block to be produced with two of its sides of a suitable shape to overlap and be overlapped by the adjacent bricks. The form of the overlapping parts *a a* may be varied, but it is believed that the form of block shown above is as convenient as any for the construction of floors and roofs of a fire-proof character.

In addition to the two sides of each block being made so as to give support to, and receive sup-

port from other blocks, the ends of each block are also so cut as to give and receive a similar support.

Fig. 3 shows a floor composed of these blocks, laid in cement, and farther held in position by tie-rods or bars *B*, at intervals, which pass through the hollow spaces formed within the blocks *A*, to plates of angle iron *C*; so that the entire thrust of the arches is received and sustained by the rods and plates *B, C*. The end of the arches thus produced may be built into walls, or carried by piers or other supports, according to the purpose to which it is to be applied, whether for the construction of floors, or roofs of houses, bridges, &c., &c. In Fig. 3 the floor is slightly canted, which would, for many purposes, be thought advantageous; but Fig. 4 shows the method of proceeding when a flat-boarded floor is to be laid upon the arch with a ceiling underneath.

In this case the tie-rods, *B*, are shown as passing below the bricks (instead of through them), and through the walls, forming supports for the ceiling joists.

Fig. 5 shows a fire-proof floor, or roof, constructed of graduated cellular bricks, with a central key-brick, forming a perfectly flat floor on the upper surface, but arched on the underside. *A* are the blocks, *B* the tie-rod, and *C* the angle iron wall plates.

Fig. 6 is a section of one of the graduated cellular blocks employed in the construction of the floor, Fig. 5. The advantages of these fire-proof floors consist in the facility and cheapness with which they can be constructed; their capacity to resist and remain unaltered by heat; their great strength, and fitness for the reception of wood floors, cement, plaster, imitation of marbles, or

* "There is a description of floor, which although not altogether fire-proof, is almost practically so. It is composed simply of plank 2½ or 3 inches thick, so closely joined and so nicely fitted to the walls as to be completely air-

tight. Its thickness and its property of being air-tight will be easily observed to be its only cause of safety."—*Braidwood on Fire-engines*;

encaustic tiles, in which case they will not exceed in thickness an ordinary floor with joists.

Arches upon this principle are well adapted for cheap and durable bridges of a moderate span, as well as for beams, girders, &c.

Persons desirous of availing themselves of this admirable invention will do well to visit Mr. Bunnett's works at Deptford, where practical demonstrations of the strength and capabilities of floors of this description may be seen and tested.

SCOTT'S COMPENSATION SELF-REGISTERING MAXIMUM THERMOMETER, FOR DEEP-SEA OBSERVATIONS.

MR. WRIGHTWORTH L. SCOTT, of Brunswick-terrace, Westbourne-grove, has favoured us with the following description of his thermometer for deep-sea observations, which was exhibited at this year's Exhibition of Inventions at the Society of Arts.

This instrument consists of a glass tube with a cylindrical bulb containing mercury (as in the ordinary thermometer) at its lower extremity; but at the top the stem is drawn on into a fine jet, bent at right angles, *A*, Fig. 1; in the interior of the second bulb, *B*, Fig. 1, this upper bulb is about half filled with mercury, the remaining space being a vacuum; near its base a platinum wire, *p*, is welded into the glass and bent upwards so that its point is nearly in contact with that of the jet. It is obvious that when the instrument is "set," i.e. the lower bulb and capillary tube to the point of the jet completely filled with mercury—any rise of temperature will expand the mercury and cause it to overflow in minute globules into the reservoir above. The platinum wire is simply for the purpose of preventing the formation of large drops at the point of the jet, by its superior attraction for the fluid metal. Upon cooling, the mercury now remaining will of course sink in the tube. The instrument is so graduated that if it were cooled to 0 deg. Fahr. the level of the mercury would precisely indicate the highest temperature to which it had been previously exposed; but if the observation were made at the atmospheric temperature the mercury would stand exactly as much higher in the tube, i.e., lower in the scale, as the temperature of the air was above 0 deg. Fahr.; therefore to ascertain the maximum temperature it is only necessary to add to the degree at which the mercury stands the temperature at the time the observation is made. Thus, supposing the "compensation" thermometer marks 35 deg., and an ordinary instrument by its side is at 50 deg., 85 deg. will be the highest temperature that has occurred since the last observation. To "set" this thermometer, the lower bulb must be gently raised until the mercury runs down the tube into the reservoir-bulb; when contact has thus been established between the two portions of the metal, the reservoir-bulb is slightly elevated, care being taken to keep the point of the glass jet under the sun-face of the metal (the dotted line *aa* in the diagram represents the level of the mercury during this operation). The mercury will now flow back into the lower bulb and refill the small vacuum produced by the previous decantation, when, upon restoring the instrument to its original vertical position, the tube will be full to the extreme point of the jet. It will be at once seen that vibration or agitation cannot militate in any degree against the accuracy of this instrument, no moveable indices being employed. Fig. 1 gives a view of the upper bulb, and a portion of the scale, of the actual dimensions. Fig. 2, one-third full size, shows a section of the entire instrument in a gun-metal tube for deep-sea experiments. Fig. 3 is an external elevation. The thermometer is "set," and inserted in the tube (into which, after greasing, a little mercury has been poured), oscillation being prevented by rings of vulcanised india-rubber, the upper one clamped by the binding screws *b b*; lastly, the cap is tightly screwed on, the arrangement being then ready for use. Well greased leather washers occupy the spaces at *ww*. The silver medal of

SCOTT'S MAXIMUM THERMOMETER.

the Society of Arts has recently been awarded to the inventor for this instrument. It has also been examined and approved by Rear-Admiral R. Fitzroy.

In a late number of the *Morning Star* we read:—"The invention of the myria-type of M. Combarieu has been submitted to the Government and accepted for inspection. This marvellous invention being destined to operate an immense and immediate revolution in the art printing, it is worth description. Hitherto the characters used in printing have been composed of a mixture of lead and antimony; these characters, by reason of their extreme softness, wear out quickly, and are, besides, very expensive. The characters are moulded one by one; the best workman can scarcely produce 5,000 of them in a day in

the rough. They have afterwards to be finished up, and pass through several hands. M. Combarieu, by an ingeniously invented machine, produces 10,000 of these characters at one stroke. Each letter is then separated by a mechanical saw, which divides them with mathematical regularity and precision. The consequence of this invention will be—production increased cent. per cent.; exactitude and regularity, hitherto unattainable; the use of harder metal, which will avoid the frequent renewal of printers' materials; reduction (by one half) of the outlay; and at length the one great object—an increase of printing, and an enormous diminution in the price of books! Look now through the vista of approaching years and behold the glorious result. M. Combarieu announces, moreover, his intention of producing characters in steel, the durability of which will be beyond calculation."

Literature.

The Globe Telegraph: an Essay on the use of the Earth for the Transmission of Electric Signals.
By SEPTIMUS BEARDMORE, C.E., F.R.G.S. London, 1859. Edward Stanford, Charing Cross.

IN July of last year, when telegraphists, perplexed with induced currents and earth currents, losses of insulation, and consequent losses of electricity, were far from sharing in the unmingled exultation with which the public of two great nations received the news of their electric union, an amateur student of electricity applied himself to the consideration of the various difficulties of ocean telegraphing, and arrived at a definite idea of the means whereby they might be overcome. This gentleman, M. Hoga, in conjunction with Mr. Piggott, well-known for his application of electricity as a medical agent, and with the author of the present pamphlet, commenced a series of experiments, which, though begun on mistaken grounds, soon assumed a scientific character. The principle on which these experiments were based, and which they served to confirm, was one which was not new in the science of electric telegraphy; though the experimenters, like many others who have laboriously explored what was already mapped out and described, were perfectly unaware of its having been previously investigated and even made the subject of a patent. Nevertheless, so far back as 1813, Mr. Bain had secured the application of simple, positive, and negative plates for telegraphic purposes; which plan, having been relinquished by the original inventor, was now adopted, and ultimately considerably extended, by the new experimenters, as a means of obtaining an electric current of low "intensity" and considerable quantity, in which the loss from imperfect insulation, and the retardation from an induced charge, should be reduced to their minimum. On the 17th November, 1858, Messrs. Hoga, Piggott, and Beardmore took out a joint patent for "Improvements in Electric Telegraphs," in which, acknowledging the prior claims of Mr. Bain, as originator of the groundwork of the system, they secured to themselves the discovery of the means by which it might be brought into practical use.

Although the value of this system is a matter to be determined by extended experiments rather than by theoretical arguments, we will place before our readers a brief *aperçu* of the more manifest advantages to be looked for in its application.

The following diagram, No. 1, represents the existing mode of employing electricity for telegraphs:—

DIAGRAM No. 2.

As in the method presently to be described, one half of the circuit is here completed by the earth in the direction of the lower arrow; the "earth plate" at the zinc end being *negative*, and that terminating the wire *positive*. From the dissimilarity of the electric character of the wire and of the earth-plate at the battery-station, results a constant tendency of the current, transmitted by

an imperfectly insulated wire, to escape to this plate by the shortest route, in lieu of completing the circuit through the second instrument and the positive plate; and hence the loss of electricity which invariably occurs in this system according to the "tension" power of the battery. In the method proposed by the inventors of the globe telegraph, these conditions are altered, as will be seen by a glance at the diagram, No. 2:—

It is evident that the current can here have no tendency to the plate whence it flows, since it cannot complete the circuit without passing through the second instrument and the opposite plate. Hence it was at first assumed by the inventors of the globe telegraph that insulation of the conducting wire was unnecessary. But, as was soon ascertained by them, the wire, if left uninsulated, would become an element in the voltaic arrangement, replacing the positive element at the station, and rendering the transmission of signals impossible.

In the lines established at the period of Mr. Bain's experiments, the loss of electricity in the existing method of working telegraphs was of little moment. In the longest submarine circuit of the present day, however, this loss of power and the induction charge caused by the electric tension, have been fatal to the success of the undertaking. And, though the tension may in this system be reduced to a certain point, yet the conditions which determine the escape of the electric fluid cannot be altered without having recourse to the current produced by the single couple of positive and negative elements.

It has been asserted, but without sufficient proof, that *tension* electricity is necessary to overcome the resistance of a wire to the transmission of the current. An idea was also prevalent, and appears to have been received by Mr. Bain, that the surface of the plates in a simple galvanic arrangement requires to be rapidly augmented in proportion to the distance between them. The ratio in which this increase is necessary has now been ascertained to be in accordance with the square root of the increase of distance. Thus, if one square inch of the metals produce a certain deflection of the galvanometer at a distance of 10 feet, 2 square inches will be sufficient to produce the same deflection at a distance of 40 feet, and 8 square inches will have the same effect when the plates are 640 feet apart. And thus, to work the cable between St. John's and Valentia, a surface would be required of less than 7 square feet of each metal. With regard to the resistance of a wire to the transmission of a current, which bears an inverse proportion to the diameter of the

an important extension of the original plan has been effected with regard to the return current, necessary to deflect a needle in either direction. To obtain this return current it is proposed to employ a metal intermediate in its voltaic character to the copper or platinum on the one hand, and to the zinc on the other. A plate of iron is found to fulfil this condition, transmitting a positive current to the zinc and a negative current to the copper. For a full explanation of the arrangement by which the three metals at either side are employed to produce the reverse signals we refer our readers to the specification of the patent, or to Mr. Beardmore's pamphlet.

The necessity of diminishing the resistance offered to the transmission of the current by the telegraphic wire is beginning to be fully recognised. It is of little avail, however, that the diameter of the main conductor should be increased, if long coils of fine wire are to be employed in the instrument through which the current takes effect. As no wire can be stronger than its weakest part, so must its power of conductivity depend upon its least-conducting portion; for any impediment in one part of an electric circuit must influence the total amount of electricity that can be transmitted. With currents of high static intensity, a long coil of fine wire is requisite; a short coil of thick wire being scarcely influenced by electricity in this condition. On the other hand, with dynamic currents of low intensity, the contrary is the case; a single turn of thick wire being very sensitive, while the ordinary coils are scarcely affected. With the increased necessity, therefore, of diminishing the resistance in the new system, increased facilities for effecting the same are also presented, and will doubtless be profited by. It is to be hoped that no time will be lost before further and more extended experiments are made to determine the practical value of an invention which appears to be called for by the requirements of the times. Its advantage in point of cheapness is but a secondary consideration, if it meets, as the *prima facie* theoretical evidence tends to prove, the difficulties which have been so fatal to the success of the Atlantic cable.

THE NEW IRON STEAM RAM.

THE following article, which we take from the *Times*, of yesterday, contains fuller information on some points respecting the Government iron steam frigate than has yet appeared:—

The English Government have very wisely determined to build a wrought-iron vessel of immense size, strength, and steam power, specially adapted as a vessel of war, and for running down ships of the largest kind, not even excepting the *Great Eastern* itself. The contract for this tremendous engine of modern war has been taken by the Thames Iron Shipbuilding Company, and sufficient progress has been made with the ironwork to be used in her to make it certain that she will be afloat and fitting for sea by June next. Her dimensions will be—extreme length, 380 feet; breadth, 58 feet; depth, 41 feet 6 inches; and her tonnage no less than 6,177 tons. The weight of the empty hull will be 5,700 tons. The engines are to be by Penn and Sons, of 1,250-horse power,

and of these we shall give a description on another occasion. Their weight with boilers will be 950 tons; she will carry 950 tons of coal, and her armament, masts, stores, &c., will amount to 1,100 tons more. Thus at sea her total weight will be about 9,000 tons, which will be driven, when so wanted, through the water against an enemy's ship at the rate of 16 miles an hour. It is difficult by mere description to give an adequate idea of the tremendous strength with which this vessel is to be built. The keel, or rather the portion to which the ribs are bolted, is made of immense slabs of wrought scrap iron, an inch and a quarter thick, and three feet six inches deep. From this spring the ribs—massive wrought iron T-shaped beams, which are made in joints about five feet long by two deep, up to where the armour plates begin, five feet below the water line. These beams are only 3 feet 8 inches apart, while, for a distance of 10 feet on each side of the keel, they are bolted in at only half this distance asunder. Five feet below the water-line the armour plates commence, and, to give room for these, the depth of the rib diminishes to about half, or nine inches. Over the ribs, and crossing transversely, are bolted beams of teak a foot and a half thick, and outside these again come the armour plates. Each of these plates is to be 15 feet long by 4 feet broad and 4½ inches thick. Several of them have been made by the company of puddled iron, of annealed scrap iron, and of scrap iron unannealed, and experiments are now being made at Portsmouth with a view of testing practically which best withstands the tremendous attack of 68-pounders. It is almost needless to say that each plate is the very perfection of material and manufacture. These ponderous slabs go up to the level of the upper deck. The orlop deck will be of wood, and 2½ feet above the keel. The main deck will be of iron, cased with wood, and 9 feet above the orlop. The upper deck will also be of wrought iron, and 7 feet 9 inches above the main. All the decks are carried on wrought iron beams of the most powerful description, to which both the ribs and iron decks are bolted; while along the whole length of the vessel, from stem to stern, are immensely solid wrought iron beams at intervals of five feet inside the ribs, which are again crossed by diagonal bands, tying the whole together in a perfect network. The armour plates are not intended to shield the whole vessel, only the fighting portion, about 220 feet of the broadside, being thus protected. This broadside, however, will mount 14 of the Armstrong 100lb. guns, which, with two broadside guns on the upper deck and two pivot guns of the same kind forward and two aft, will give her a total armament of 36 guns, each throwing a 100lb. shot over a range of nearly six miles. Neither the bows nor stern have any of the large armour plates, but are coated with wrought iron plates of nearly one inch and a half thick over two feet of teak, which will offer sufficient resistance to prevent most shots from going through. But to compensate for this apparent deficiency both bows and stern are so crossed and recrossed in every direction with water-tight compartments that it is a matter of perfect indifference whether they get riddled or not, and each of these ends are shut off from the engine-room and fighting portion of the ship by continuous massive wrought iron transverse bulkheads. So that, supposing it possible that both stem and stern could be shot away, the centre of the vessel would remain complete and impenetrable as ever, still offering in all 24 inches of teak coated with 5 inches of wrought iron to every shot. But both stem and stern are built inside of such immense strength that coating with armour plates would be almost superfluous. The bows, as the spot where the whole shock must be received in running down ships, are inside a perfect web of ironwork, strengthened back to the armour plates with no less than eight wrought iron decks an inch thick, and crossed and recrossed in all ways and methods with diagonal bracings and supports. In the design sent into the Admiralty by the Thames Shipbuilding Company the shape of the bows was made exactly after the outline of the

neck and breast of a swan when swimming. Thus the point which would strike an enemy's vessel was the "breast," which was placed under the water line. In the Admiralty model, according to which the "ram" is to be built, the bows form an obtuse angle, the point of which is just level with the water, receding back at a rather sharp slope both above and below it. This peculiar shape, however, will be concealed under the usual figurehead and forward gear with a light artificial cutwater of wood, so that apparently the vessel will be an ordinary frigate of the largest size. The Admiralty, no doubt, intend by these devices to disguise her real character, but we need hardly point out how utterly futile such an attempt would be. Could any naval officer be deceived by any amount of painting about the character of a ship of 6,000 tons, nearly 400 feet long, rigged like a three-decker, yet only carrying a broadside of 14 guns on her main deck? Or do the Admiralty suppose that there will not be perfect photographs of her, when finished, taken for all the foreign powers, which will be reproduced and distributed among their navies, with strict injunctions in case of war always to avoid such a vessel if they can? The very idea of attempting to conceal the real purpose of a vessel so remarkable, and the only one of its kind afloat, seems absurd. Coming up into action with other first-rates in line of battle, no doubt she would pass muster unobserved, but under such circumstances, even if as well known to the enemy as to the English, the knowledge would avail nothing to the former. Once a general engagement was commenced, the "ram" would be able to pursue her mission of destruction by running into the sterns of the enemy's vessels almost without hindrance. When such is avowedly her purpose it seems, to say the least, unwise to cumber her with the masts and rigging of a line-of-battle ship. The shock of striking the first vessel would bring down all her masts by the board like reeds, and leave the ram's decks so encumbered with wreck as might even render her almost useless for further efforts. The mode in which she attacks will be to run straight at the enemy, taking him, if possible, in the stern or quarter, all the men on deck retiring to the stern to avoid injury from falling spars. When about half the vessel's length from the enemy the engines are to be stopped, and the engineers stand by to reverse the engines in order to clear her from the wreck of her antagonist before the latter goes down. It is calculated that striking a line-of-battle ship in the stern the ram would sink her within three minutes. The bowsprit will, we believe, be telescopic in order to be housed on board with the anchors before striking the enemy, that there may be no chance of becoming entangled with the wreck of the sinking vessel. It is, however, yet to be explained how she is to get rid of her own wreck of masts and spars, and above all what precautions will be adopted to prevent any chance of the rigging fouling her screw. The cost of the hull will be about £200,000, the engines about £75,000, and her fitting for sea about £45,000 more—or £320,000 in all. If she only does one-half of what may be fairly anticipated from her she will be cheaper to the nation than a dozen sail of the line, and we hope before long to announce that another of the same kind has been decided on.

CLIFFORD'S SYSTEM OF LOWERING BOATS.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN:—I must beg space in your columns for a reply to the objections urged by "Nauticus" against my system of lowering boats, as they are evidently made by one who does not understand the principles of the system, or know how to work it properly. Before answering these I would remark that the impression evidently intended to be conveyed by the report in the *Times* could only be that the "operation" referred to as requiring four men was that of the "system of lowering" invented by Captain Kynaston mentioned in the sentence immediately preceding, and not the

disengaging hook only, which would be simply ridiculous. Four men is certainly no over estimate when he himself admits that the *usual number* are required on board to lower, with one man to disengage; printed directions furthermore stating, that "the foremost disengaging fall may be kept handy; but it should only be used as a resource to provide against the extreme possibility of the aftermost line being foul, which latter is hardly possible." This would involve the necessity of the presence at least of a second for disengaging. "Nauticus" further states, "whether the men lower simultaneously or not, directly the disengaging line is let go the boat *must enter the water on an even keel*." What is to prevent one fall going, with a run? a common consequence of lowering by the falls, which no system of disengaging can remedy. To the first objection, that the length of the pendants cannot be suited to light and heavy draughts, the reply is, they are adjusted so as to enable the boat to reach the water when the ship is laden, but extra rope is allowed for light draughts, as my printed directions explain. In men-of-war the difference in draught with coals or without is so slight as to be of no consequence in this matter, and the additional rope on the roller could not lead to accident. In a line-of-battle-ship the extreme variation of draught would be 20 inches; in ships of the "Diadem" class, 2 feet; and in gun-boats 6 inches. From the way in which the boat hangs, by my system (the points of suspension head and stern being above the boat's gunwale, from which steadying lines to the boat's sides are attached), she would not be swamped as a boat is ordinarily under such circumstances, if the water were moderately smooth, and if rough, the fall of the wave would at once clear the pendants. "Nauticus" cannot tell me of any instance of a boat "having been swamped and her crew probably drowned," nor can he produce the instance which he "fears might be cited."

One of the chief features of my system of disengaging, and to which I attach very great importance, though the one least understood till seen in actual operation, is that when the boat is lowered, steerage way is not only put upon her directly she touches the water, but is retained for several seconds after she is floating by a gradually yielding strain without any sudden check or additional act of any one to release the boat. This enables her to be sheered clear of the ship, and out of the suction of the screw. The loose tapered end of the pendant as it is overhauled through the three sheave blocks accomplishes this end, either by the strain caused by the way of the ship, or if at anchor, as the boat falls with the wave or is drifted away. Without some such provision, lowering a boat from a screw steamer under way, especially on the weather quarter in a heavy seaway, would be a dangerous experiment, the wind and draught of the screw carrying the boat directly on to the latter. But this I have repeatedly done on public trials.

As to the boat being stove against the ship's side, the celerity obtained by lowering with single pendants is the best possible prevention to such a casualty; for when lowered and disengaged at the same time by one hand only, advantage can be taken of the roll of the ship, and the boat be dropped on the water *clear of the ship in a few seconds* after the word of command is given to "lower away," if the gear is only kept in the same condition as the rest of the running gear of the ship. This cannot be done where the combined action of several men is required, as in lowering by the falls.

As to the stiffening of the pendants, the same causes that would prevent their working would operate against the falls; and if the pendants, from being of stouter rope, offer greater resistance to a free run, the direct action of the weight of the boat on the pendant or the single part of rope only that they involve, in place of the four parts of rope used in the falls, is a proportionate power to overcome such resistance.

The "vibration" complained of in lowering could only arise from the gear being improperly rove,

and the pendants being passed round the sides or cheeks of the blocks, preventing a fair and even run. This would account for "sundry of the crew" being required to overhaul the pendants and for ropes being cut. Cases can be substantiated where this has happened. Rope, moreover, has been supplied from one yard of a character contrary to my printed instructions, and it is this cause, and not the nip on the rope, that has led to their breaking. The attention of their lordships will be officially directed to this point, as it is *only* with the rope in question that any fracture has ever occurred. After three years (compulsory use) in all Government emigrant and transport ships no single case of rope breaking has been reported to the authorities.

My plan does not pretend to do more than lower evenly and safely and disengage at the same time, *by one man*, and I cannot help drawing attention to the testimony "Nauticus" bears to its efficiency, in the facility which he says it affords for suddenly leaving a ship—the very purpose for which it was intended—and which has been officially declared a "*desideratum wanted throughout the naval service*." This very admission is the best contradiction to the objections that have been previously urged. The occasional abuse, however, of a public good cannot be urged as a reason for its suppression. Besides, in times of danger, when the power of lowering is in the hands of one person, any trustworthy man ordered to the command of such a means by the captain or officer on watch, in having the entire control of everything connected with the lowering and disengaging in his own hand, can stop descension and prevent the mischief arising from hurry and confusion, or take advantage of the instantaneous action that such a system would afford to escape at the proper moment.

As to a stopper being necessary for taking the strain off the pendants when the boat is hanging at the davits heads, "Nauticus" must know something of the kind is always used to relieve the falls.

Written correspondence must always be an unsatisfactory way of solving the mechanical objections urged in favour of rival inventions, and I know I have already trespassed on your indulgence; but if "Nauticus," or any officer in Her Majesty's service, will tell me of any position, either by day or night, from a ship at anchor or under way, from the lee or weather side, in smooth water or a heavy rolling sea, when a boat fitted with my plan could not safely be lowered, I will myself attend in person, and try it against any other system or invention that can be brought against it for effecting a like end. It is after such times and occasions that judgment should be passed, and it is such practical tests that "Nauticus" should endeavour to bring about, as well for the public good as to settle the question of the competing ideas of himself and

Yours obediently,

C. CLIFFORD.

Temple, June 20, 1859.

RIFLES FOR VOLUNTEER CORPS.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE." GENTLEMEN,—At a numerous meeting held by the gentry of Sussex at the Hayward-heath station, on the 22nd inst., Lieutenant Busk, of the Victoria Rifle Corps, read a most lucid paper on the properties of the rifle, which was received with reiterated plaudits, and most deservedly so. I had the happiness to be present, and can safely say that the enthusiasm manifested by the gentlemen composing the meeting will find an echo throughout all England. The choice of the proper rifle for volunteers is now a matter for grave consideration. I do not hesitate to prefer the Lancaster muzzle-loader to the Enfield. A most clear description of the practical results of both weapons, as evinced from their use in the late war in India, appeared recently in the *Times*. It was written, I believe, by Sergeant Sturrock, of the Royal Engineers, than whom a more perfect master on the subject of the rifle, and its now

various missiles, I never conversed with. In support of my preference for the Lancaster rifle as a military arm, I will state that I lately met a sergeant of the 98th Regiment, now stationed at Plymouth, who informed me that he had fired forty rounds in succession from the Lancaster rifle, using pure suet or tallow for the lubricating matter, without finding the slightest inconvenience from loading. The sergeant had received honours and increased pay for his excellence as a marksman, and therefore must be a good authority on the superior efficiency of the Lancaster rifle.

As regards breech-loading rifles, I have a high opinion of that invented by Mr. Leetch, of 68 Margaret-street, Regent-street.* As a proof that I think well of it, I have ordered one to be made for me, to use when I become a guerilla, in conjunction with some hundreds of thousands of the "bone and sinew" of the land. It is a source of pride to me in my advanced stage of life, to be able truly to say that as far back as the year 1823, I had perfected my elongated rifle shot and shell, and thus evoked "the strength that slumbered" in a rifled arm. I am, Sir, yours, &c.,

J. NORTON.

Rosherville, June 25.

UTILISING THE MILLIONS.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—As it appears there is no use now made of the fifty millions of iron cups for inserting in the hollow base of the Minié rifle shot, which were manufactured by Mr. Greenfield by order of the War Department, I make use of them in forming the head and front of my elongated rifle shells. I am, yours obediently,

J. NORTON.

Rosherville, 28th June.

Proceedings of Societies.

THE GEOLOGICAL SOCIETY OF LONDON.

June 15.—Prof. J. Phillips, President, in the chair. Special General Meeting. It was resolved that persons proposed after November 2nd, 1859, for election as Non-resident Fellows of the Society should pay an entrance-fee of £6 6s., and an annual subscription of £1 11s. 6d. Ordinary General Meeting. Major W. E. Warrand, Bengal Engineers, Westhorpe, Southwell, Notts, was elected a Fellow. The following communications were read:—1. "Notes on Spitzbergen." By J. Lamont, Esq. Communicated by Sir C. Lyell, V.P.G.S. 2. "On the Formation of Gypsums and Dolomites." By T. S. Hunt, Esq., of the Geol. Surv. Canada. Communicated by Prof. A. C. Ramsay, F.G.S. 3. "On the Tertiary Deposits, associated with Trap-rocks, in the East Indies." By the Rev. S. Hislop. With descriptions of the Shells by the Rev. S. Hislop; and of the insects by A. Murray, Esq. Communicated by the President.

ROYAL AGRICULTURAL OF ENGLAND.

June 22.—At a Special Council, his Grace the Duke of Marlborough, President, in the chair. The report of the Special Committee appointed to examine the past accounts of the Society was read, received, and confirmed. It was moved by the Hon. Col. Hood, and seconded by Lord Berners, "That Mr. Hudson be dismissed from the office of Secretary." On the motion of Mr. Brandreth, seconded by Col. Challoner, it was resolved, "That a Committee be appointed consisting of the President, Vice-presidents, Trustees, and the following members of the Council:—the Hon. Col. Hood, Mr. Barnett, Mr. Jonas Webb, Mr. Wren Hoskyns, Mr. Torr, Mr. Fisher Hobbs, Mr. Milward, Mr. Brandreth Gibbs, Mr. Amos, and Mr. Brandreth, to take into consideration and report to the next general Council what in their opinion should be the general and particular duties of the secretary and the mode of his appointment." Col. Challoner, Chairman of the Implement Committee, presented the report recommending the judges of implements for the Warwick Show. Mr. Milward, Chairman of the Live Stock Judges Committee, presented the report recommending the judges of live stock, cheese, and wool. Those reports were received and confirmed. Mr. H. S. Thompson, Chairman of the Journal Committee, reported the recommendation that the Prize of 25 Sovereigns for

* Described and illustrated in our last number.—Eds. M. M.

the best Report on the Agriculture of the Islands of Jersey, Guernsey, Alderney, and Sark, be awarded to the author of the essay bearing the motto "Practical." The sealed envelope having been opened by the President, the author was declared to be C. P. Le Corme (Honorary Secretary to the Royal Jersey Agricultural Society), Beaumont, Jersey.

Kiln Case.

COURT OF QUEEN'S BENCH, Westminster, June 25. —(Sitting at Nisi Prius, before Mr. Justice Hill and a Special Jury.)

DOULTON v. STIFF.

Mr. Bovill, Q.C., Mr. Lush, Q.C., and Mr. Webster appeared for the plaintiff; Mr. Knowles, Q.C., and Mr. Hindmarch for the defendant.

The plaintiff in this action, Henry Doulton, was one of the partners in the firm of Doulton and Co., of the Lambeth Pottery Works, and he sued the defendant, James Stiff, also a Lambeth potter, to recover damages for the infringement of a patent granted to the plaintiff on the 11th of May, 1854, for "improvements in kilns used in the manufacture of stoneware, earthenware, and china," and described in a former volume of the *MECHANICS' MAGAZINE*. The defendant pleaded several pleas, denying the infringement, and also the novelty of the plaintiff's invention.

The object of the plaintiff's invention, as described in his specification, was so to arrange the fireplaces or furnaces of kilns used in the manufacture of stoneware, earthenware, and china, as to prevent as much as possible the evolution of smoke into the atmosphere. For that purpose, over each fireplace or furnace, a fire-tile or thick plate, perforated with numerous holes, was placed or fixed, and over that a chamber was formed to receive air, there being a slide or other means of regulating the flow of air into the chamber. By that arrangement the perforated tile or plate became highly heated by the fire below, and the draught of the fire being inward to the kiln, the air would pass down through the perforations and become still more highly heated than when in the chamber above; and the heating of the air in the chamber might be assisted by having perforated or other plates or surfaces in the chamber, so that the air might become heated by passing in contact therewith. By such means of obtaining a supply of heated air to that class of fires, it was stated the fuel would be better burnt and the evolution of smoke into the atmosphere prevented. The plaintiff then described the arrangements by which he effected his object, and stated that by those arrangements the perforated tiles would become highly heated, and the atmospheric air would become heated in passing from the chamber downwards through the perforated tiles into the upper part of the furnace or fireplace, and would enter above the fuel therein, and thence pass into the kiln through the opening, where it would meet with the products passing off from the fuel, and become ignited with them as they entered the kiln. The parts of the kiln and the parts of the fireplaces or furnaces shown by the drawings were similar to those in ordinary use, and the novelty consisted in the application and arrangement of the parts shown and described for admitting and heating the air.

Several witnesses were examined on the part of the plaintiff, to show the novelty of his invention, and its infringement by the defendant. According to their testimony the effect of the invention when it had been adopted had been, by producing a more perfect combustion, to abolish smoke, and so to do away with the nuisance which was formerly caused by the Pottery Works.

On the part of the defendant several witnesses were called, who did not deny that by the plaintiff's method smoke was prevented; but they said there was no novelty in his invention, and that the same arrangements were already in use, and were shown in Ferguson's patent of 1853, which had been abandoned. They also went so far as to say that even with the old Staffordshire kiln it entirely depended on the fireman whether or not there should be any smoke.

Mr. Knowles and Mr. Bovill having addressed the jury for their respective clients,

The learned Judge summed up, and said there were two points for the consideration of the jury—first, whether the defendant had infringed the plaintiff's patent; and secondly, whether the plaintiff's invention was new. Both those questions would require to be answered by the jury. The first question, in fact, involved the second. The plaintiff's patent was not for one machine, or a single arrangement, but for a combination. There was no doubt that the defendant had not used all the combination put forward by the plaintiff, but it was alleged by the plaintiff that the

defendant had used a portion of the combination, and he had to tell them that in point of law, that might be the case if the part of the combination was new and material. If the defendant had used an immaterial part of the combination, then the defendant had not infringed the patent; if he had used that which was not new, it was no infringement of the patent. The jury must be satisfied that the defendant had used a part of the combination which was invented by the plaintiff, and which was new and material. The learned judge then proceeded to read over the whole of the mass of evidence. Mr. Carpenter had stated that, in his opinion, it was impossible for the old Staffordshire kiln to consume the smoke, and yet there were three witnesses who had tried the experiment, and they positively swore that it did consume the smoke. That was a fact against scientific opinion. The plaintiff appeared to put great stress on the perforated tiles, and those the defendant had not used.

The jury retired for some time, and then said the defendant had infringed the patent, but that the combinations used by the defendant were not new.

The Judge: Then this is a verdict for the defendant.

Our Weekly Gossip.

We have frequently given a word of commendation to the *Photographic News*, and had both hoped and heard that its success as an organ of photographic science and art was assured. We now fear, however, that it must be otherwise. We judge so from the fact that its managers are beginning to nibble at subjects on which it has not the shadow of a claim to speak, and which its title in no way includes—a sure sign, we presume, of a want of success in its own sphere. For example, in its last number the greater part of a page is devoted to gossiping remarks on a method of ventilating public buildings, and especially hospitals—a pretty topic for elaborate treatment in a "Photographic" journal! With how little sense the subject is treated may be inferred from the fact that while the person of the inventor himself is minutely described, not a word affording any clue to the nature of the invention itself is given. We venture to recommend "Photography" rather than "Ventilation" to the attention of the editor.

This week's Number of *All the Year Round* contains an article entitled "Change for Nuggets," upon the processes of money-making at the Royal Mint. The account which it gives of the several processes is, as might be expected, very meagre, as compared with the elaborate articles on this interesting topic now in course of publication by ourselves. This will be seen on comparing the following description of the weighing-room with the account of the same apartment given in our last number. The close resemblance between some of the reflections in this week's article of *All the Year Round* and our last week's article will also be apparent. The writer says:—"From the noise and clatter of the cutting-room I was conducted to the elegant calmness of the weighing-room, a department handsomely fitted up, and looking like a show-room for elaborate chronometers. Here is performed one of the most interesting and delicate operations throughout the whole Mint. Upon the counter, on ornamental iron stands, is a silent council of thirteen automaton balances, who pass judgment, individually, upon the work in the foregoing departments, and decide with unerring exactness upon the weight of the golden dumps. These automaton judges sit under glass cases, to preserve them from damp and dust, and they have the appearance of being a row of French skeleton clocks. The golden dumps that are passed into the weighing-room, still looking like the aforesaid Irishman's brass button, are distributed amongst the balances, passing down a receiving slide on to a strip of steel. This strip of steel is made to advance and recede at certain intervals, perhaps of a quarter of a minute, and at each advance it pushes a blank on to a beautifully poised scale table, sensitive to the slightest variations of weight. For a few seconds the machine appears to reflect, and then the golden dump is gently pushed off the scale by the arrival of another piece on the steel slide for judgment. The first, if "heavy," disappears down the outer one of three flattened tubes; if "light," down the inner one; and, if quite correct in weight, down the centre compartment. By careful manipulation much of the work is now made to fall in the medium boxes, thereby effecting much saving in the annual expenses of the Mint—a reform that is attributable to the present working master and his superintendents."

The Government return of "gold, silver, and copper monies of the realm" struck at the Mint during the

year 1858 has been published. It shows that of sovereigns there were coined 803,334, representing, of course, an equal value; of half-sovereigns, 855,578, value, £427,789 5s. 9d.; where the 5s. and 9d. are here obtained to us, however, does not appear; of florins, 2,239,380—value, £223,938; of shillings, 3,108,600—value, £155,430; of sixpences, 1,983,480—value, £48,312; of groats, nil; of threepences, 1,445,023—value, £18,074 2s.; of Maundy monies, consisting of silver fourpences, threepences, twopences, and pence, and distributed by Her Majesty's almoner on Maundy Thursday to certain pensioners at the Almonry, Westminster, 20,988; value, £193 11s. 6d. Of copper monies, there were struck, of pence, 1,559,040—value, £6,496; of halfpence, 2,472,900—value, £5,152; of farthings—neglected farthings—1,720,320—value, £1,792. In addition to these items, and which do not figure in the return alluded to, we are in a position to state that the Mint produced during the last year 15,000 Persian, Indian, and Kaffir medals, and rather over four millions of 20-cent., 10-cent., 5-cent. silver and one cent. bronze coins for Canada. In another part of our journal will be found a note on the workings of the Mint at present. All tends to prove that that place requires expanding if it is to keep pace with the demands made upon it. Why not have a second exclusively copper mint, like Calcutta is doing?

Mr. B. L. Phillips writes:—"Your readers may remember some particulars were given in July and August, 1854, relative to my discovery for purifying iron. I have not till recently had an opportunity to make further trials at the Monkbridge Works, Leeds (Messrs. Jas. Kitson and Sons); but I now hand you the results of some experiments there in the puddle-furnace. The effect produced on the metal appears astonishing. Part of the experiment No. 2 was made into $\frac{1}{2}$ and $\frac{3}{4}$ in. rods, and submitted to most severe tests, by bending, twisting, and tying into the treble knot, all of which it stood without the least deflection, and it was pronounced fully equal to the wellknown make S. G. The metal made by this process when struck vibrates like steel, thereby showing its purity and strength. For rails, electric wire, springs, chain cables, and indeed for all work requiring good, sound, and pure metal, I think this make will prove invaluable, and be an ultimate saving of 15 to 25 per cent., from its superior tenacity and durability. Not being practically engaged in the trade, I labour under every disadvantage, in not being able fully to carry out the required experiments in the puddle and blast-furnace, and also in the make of steel, but I am willing to treat with any respectable firm for that purpose, and call the attention of the trade to the following particulars, being convinced that my invention will prove the most important discovery of our time, should its further development carry out the facts which the specimens indicate." We do not think it necessary to publish the results of experiments.

CAPTAIN KYNASTON'S DISENGAGING HOOKS.—The *United Service Gazette* says:—"The Cadmus, 21, screw, Captain Hillyar, made a trial trip outside Plymouth Sound on Monday. Her engines, which are by Penn, worked admirably, and the speed obtained was 11 $\frac{1}{2}$ knots. The first cutter fitted with Kynaston's life-hooks was lowered while the ship was going nine knots, having besides her proper crew, Admiral Kingcome, and Mr. Ward, Assistant to the Chief Engineer at Keyham; and subsequently when going ten knots, the other cutter with two lieutenants and some young ladies, in all sixteen persons. The process of disengaging was so simple and easy, that the party could scarcely believe they were clear of the ship until they saw her a hundred yards away from them. The Cadmus sailed on Wednesday for the Mediterranean. The Curacao, 31, screw, Captain Mason, at Plymouth, has had her quarter-boats fitted with Kynaston's life-hooks, in lieu of the patent boat-lowering gear previously in use."

NOTICES.

THE letters of Mr. Baker (Inland Revenue Department), and of Mr. J. P. Drake, are unavoidably left over until next week, as are the notices of several publications also.

THE MECHANICS' MAGAZINE will be sent free by post to all subscribers of £1 ls. 8d., annually, payable in advance. Post Office Orders to be made payable to R. A. Brooman, at the Post Office, Fleet Street, London, E.C.

TO ADVERTISERS.

All Advertisements occupying less than half-a-column are charged at the rate of 5d. per line for any number of insertions less than 13; for 13 insertions, 4d. per line; and for 52 insertions, 3d. per line.

Each line consists of 10 words, the first line counting as two. Wood-cuts are charged at the same rate as type for the space occupied.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgement:—

STEAM ENGINES, &c., 2624, 2625, 2634.
BOILERS AND THEIR FURNACES, 2641.
ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 2507, 2605, 2637.
SHIPS AND BOATS, including their fittings, 2596, 2627.
CULTIVATION OF THE SOIL, including agricultural and horticultural implements and machines, 2607, 2635.
FOOD AND BEVERAGES, including apparatus for preparing food for men and animals. *None.*
FIBROUS FABRIC, including machinery for treating fibres, pulp, paper, &c., 2599, 2603, 2606, 2611, 2612, 2614, 2618.
BUILDINGS AND BUILDING MATERIALS, including sewers, drain-pipes, brick and tile machines, &c. *None.*
LIGHTING, HEATING, AND VENTILATING, 2604, 2613, 2632.
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 2598, 2608, 2615, 2623.
METALS, including apparatus for their manufacture. *None.*
CHEMISTRY AND PHOTOGRAPHY, 2600, 2622.
ELECTRICAL APPARATUS, 2601, 2616, 2620.
WARFARE, 2610, 2631, 2633.
LETTER PRESS PRINTING &c. *None.*
MISCELLANEOUS, 2610, 2613, 2617, 2618, 2620, 2621, 2627, 2628, 2629, 2630, 2636, 2638, 2639.

2596. H. DOUGLAS. *Improvements in screw propellers.* Dated Nov. 17, 1858.

Here the inventor forms the advance edge of the propeller blades of a convex curved form so that the curve of the edge of the blade at the extreme end or periphery will be in the rear (as regards its position in the screw) of the inner termination of the curve, or that next the centres the curve is such that it produces an easy elevating action in the water. The leading edges of the propeller blades are sharpened or serrated so as to clear the propeller from cordage, &c. *Patent abandoned.*

2597. W. CLARK. *An improved bit or bridle for horses.* (A communication.) Dated November 17, 1858.

This bit is composed of a system of levers terminated by spoonbills or blades, which, by suitable reins, will approach and close the nostrils of the horse and suspend his respiration, and thus compel him to obey. *Patent abandoned.*

2598. S. RILEY. *Improvements in the manufacture of hats, bonnets, and caps.* Dated November 18, 1858.

This consists in the application of any kind of elastic material to any part of the body or brim, either outside or inside of either hats, caps, or bonnets. *Patent completed.*

2599. C. COWPER. *Improvements in assorting and separating combed fibres, and in machinery for that purpose.* (A communication.) Dated November 18, 1858.

This invention is similar to those formerly patented by Mr. De Jough. The present invention, however, is adapted for operating on fibres, when in the form of a sliver or band, instead of being in separate sticks or bundles. One or more slivers of combed fibres are fed into the assorting machine by a feeding apparatus composed of a gill or porcupine roller, which brings forward and delivers such fibres, so that their projecting ends may be lashed into a travelling comb, where the ends of the fibres so lashed are held by a suitable apparatus, so that, by the back motion of the feeding apparatus, the fibres so held or nipped shall be drawn through the teeth of the feeding apparatus and detached from the sliver and left in the travelling comb. The travelling comb or holding surface will then carry forward such detached fibres, the projecting ends of which should be supported and held up in their proper position by suitable holders or guides, until the needles of one or more travelling combs working parallel to, and at the same speed as, the first-mentioned one, enter the projecting ends of the fibres, so as to leave projecting beyond the outermost travelling comb a length of the said fibres sufficient to be taken hold of by the first drawing-off or nipping apparatus, after which, as the travelling combs go forward, the outermost travelling comb goes away from and leaves the fibres, and so presents a fresh projecting end ready to be taken hold of and drawn off by a second drawing-off or nipping apparatus, which is set nearer to the first-mentioned travelling holding comb, into which the fibres were lashed, and so on for each travelling comb, of which there may be one, two, or more, till the shortest fibres are drawn off from the first travelling holding comb. *Patent completed.*

2600. E. BRIGLIET. *The obtaining of caloric by a new chemical and mechanical process.* (A communication.) Dated Nov. 18, 1858.

This invention is not described apart from the drawings. *Patent completed.*

2601. SIE C. T. BRIGHT. *Improvements in insulators, and an improved mode of connecting insulators to posts and other supports.* Dated Nov. 18, 1858.

This invention was described and illustrated at page 364, No. 23, of the MECHANICS' MAGAZINE (New Series). *Patent completed.*

2602. J. and H. SHARP. *Improvements in Jacquard machines employed in weaving.* Dated Nov. 18, 1858.

This relates to working the cylinders or producing the oscillating motion thereof required in Jacquard machinery, and the improvements consist in causing the cylinder to

beat up the cards thereon, to act upon the needles at such time only as they are free to move, or when the "griffo" or lifters have not hold of the hooks. *Patent abandoned.*

2603. H. STORR. *Improvements in warping mills, or apparatus connected therewith.* Dated Nov. 18, 1858.

This consists in the use of a heck or apparatus for separating or "taking the lays" at the tail end of the warp. It is formed similar to the heck now in use for taking the lays at the head end of the warp, but instead of having eyes or holes for the threads to pass through, forks or slots open at the top, so that the separate lays can be lifted out at the openings thereof, are employed. *Patent completed.*

2604. J. LESLIE. *Improvements in the manufacture of gas.* Dated November 18, 1858.

This consists in subjecting mineral bituminous matters to distillation at low temperatures to obtain the products distilled over in a condensed liquid form, and then to subject such liquids to processes of purification, in order to fix or remove the ammonia, sulphur, &c., and then to subject the purified liquids to destructive distillation, by which a very pure gas is obtained. *Patent completed.*

2605. J. OAKES. *Improvements in the manufacture of spurs.* Dated November 18, 1858.

This consists in manufacturing spurs by striking or stamping them into form in suitable dies. *Patent completed.*

2606. J. M. MILLER and J. FEAR. *Improvements in machinery for winding fibrous substances or materials when in the form of thread or yarn, on to the bobbins or wheels used in lace machinery.* Dated November 18, 1858.

The object here is to enable a number of bobbins or reels to be wound at one time independently of each other under the superintendence of one person, so that each may be equally filled, that the thread or yarn may be kept steady while being wound on, and be readily cut, and that the reel may be prevented from overrunning. The patentees employ a revolving knife for cutting the thread, &c., at the proper time. They prevent overrunning by effecting the stoppage of the reel by pressure on the reel itself when the thread, &c., is cut or broken, and they keep the thread, &c., in a constant state of tension, steady it and prevent vibration by a peculiar contrivance. We cannot afford space for the details of the invention. *Patent completed.*

2607. D. STOTEN. *Improvements in ploughshares.* Dated November 18, 1858.

This consists in the application of hardened steel to the points of ploughshares. *Patent abandoned.*

2608. E. T. ARCHER. *Improvements in hat ventilators, and appliances connected therewith.* Dated Nov. 18, 1858.

This consists in a method of making and fixing a brass ventilator in hats, in connection with which is a steel spring for holding railway tickets, cards, &c. *Patent completed.*

2609. B. RIDER. *Improvements in ventilating hats and caps, and in the preparation or manufacture of the material of which those articles are made.* Dated November 18, 1858.

This consists in ventilating hats, &c., by perforating the bodies before the silk or other covering is applied. The covering hides the perforations, but permits of the passage of air. It also consists in combining with paper, while in a state of pulp, long fibres of any fibrous material, or fibres or threads of cork for the production of material for the manufacture of hats, &c. *Patent completed.*

2610. P. E., and J. MARCHAND. *A new process for refining lamp oil.* Dated November 19, 1858.

The inventors take ten hectolitres of the oil of sesame, or linseed, or any other sort, which, being clarified, is poured into a boiler heated by steam or hot water. When heated to 75°, 3 per cent. of alkali at 28°, mixed with one-third of salt, is poured in, and a pale oil, without smell or taste, is the result. This oil is next mixed with a certain quantity of waste or cake of native rape seed, turnip seed, or mustard seed of China, the whole put under the stampers, and subsequently submitted to the hydraulic press. The oil thus produced is boiled with 3 per cent. of sulphuric acid and 10 per cent. of water; and, after being left to stand, is passed through a filter of charcoal or sawdust. *Patent abandoned.*

2611. J. BROWN. *Certain improvements in index and Jacquard machines.* Dated November 19, 1858.

The object here is to dispense with the weights and springs in index and Jacquard machines to draw down the heads or harness. For this purpose the inventors make use of two griffo, one of which raises the hooks up and the other depresses them. These griffo act upon a double hook of an improved shape, or upon two hooks of the usual shape: the hooks are connected to top and bottom jaws. It also consists in a mode of turning round the Jacquard cylinder. To the Jacquard cylinder is fixed a bevil-wheel, gearing into another bevil-wheel, loose on a shaft, which is driven by the crank-shaft or tappet-shaft of the loom. This wheel has catches taking into a catch-box fixed on the said shaft, and sufficient play is left between the catches to allow the cylinder to be moved from the needles before it is turned round. There are modifications included. *Patent abandoned.*

2612. W. S. HAYWARD. *Improvements in the manufacture of a glutinous and viscous substance or doctrine to be used in the manufacture of paper, and in dressing textile fabrics, by which greater tenaciousness, smoothness of surface and body are obtained.* Dated November 19, 1858.

Here the patentee first subjects the starch to the action of a weak solution of nitric or nitro-sulphuric acid, sprinkling the latter over it; the strength of this solution will vary and depend upon the quality of the starch used; generally a useful preparation will be one of acid to 25 of water, and the quantity of solution used may be about an eighth or tenth of the mass of starch operated upon. He then subjects the whole mass to the action of heat, and this preferably by an arrangement so that an equable temperature may be maintained, as by a sand, air, or steam bath. He continues the action of the bath until the liquor is evaporated, and so long as no change takes place in the colour of the resulting product. He then removes it, and grinds it down to a powder. *Patent completed.*

2613. G. HOWE and J. NORTON. *An improved method of boiling water or worts for breweries, distilleries, &c., by steam, or for heating rooms, public buildings, churches, chapels, factories, &c.* Dated November 19, 1858.

The patentees fix their apparatus to any ordinary boiler, by attaching an outlet-pipe to the same, with taps and valves, which pipe connects the water or steam with a coil pipe, which coil pipe is introduced into a boiling pan or vat, thereby causing the liquid in the pan or vat to boil quickly. The pipe is then carried from the pan or vat into the boiler, thereby returning any condensed or waste steam. *Patent completed.*

2614. S. C. and J. LEACH. *Certain improvements in the construction of "self-acting temples," to be employed in looms for weaving.* Dated November 19, 1858.

This consists in the use of wooden rollers revolving upon an axis, each furnished with pins or points, and with guards or covers moving upon the same axis. These rollers or temples are mounted at each end of a horizontal bar, which extends across the loom (its upper surface being level with the peripheries of the temples), and is jointed near the middle of its length to be adjustable to the width of the loom, and also at each end for the adjustment of the temples. The horizontal bar is riveted or hinge-jointed upon brackets, so that it may vibrate laterally upon such brackets, which are secured to the framing of the loom. The fabric is distended between the temples, and bears upon the upper surface of the bar, which has the effect of distending the fabric in a direct line across the loom, and of preventing the usual curving thereof, as when any uneven strain is exerted upon the fabric, the temples and bar move laterally, and thereby equalize the tension of the fabric. *Patent abandoned.*

2615. J. EDWARDS. *Improvements in the manufacture of trouser buttons.* Dated November 19, 1858.

This relates to the use of prepared paper, &c., to the manufacture of trouser buttons, so arranged as to form the front of the buttons, or placed between the back and front after the front has been ornamented by piercing, so as to allow the paper to show through the opening, and for colouring the same in the way that steel pens are coloured. *Patent abandoned.*

2616. W. HANCOCK. *Improvements in the manufacture of electric telegraph wires and cables.* Dated Nov. 19, 1858.

This consists in the use, as an insulating material, of a compound composed of gutta-percha, or india-rubber, of a shellac, resin, Venice turpentine, &c. Also, in the preparation of the conducting wire by passing it through a cement composed of asphaltic or bitumen, and Venice turpentine, either with or without the addition of shellac, resin, &c. *Patent completed.*

2617. C. F. VASSEBOT. *An improved apparatus for condensing and cooling vapours and liquids.* (A communication.) Dated November 19, 1858.

This consists of a cylindrical vessel divided into two portions, an inner and an outer, each possessing nearly the same sectional area. A pair of copper sheets is placed parallel, having a small space between their surfaces; these sheets are then wound spirally within the outer portion of the cylindrical vessel. At one extremity of the said vessel is a series of tubes, communicating at one end with the spaces between each of the convolutions of the copper plates, and with their other ends terminating in a vessel of cold water, which is applied for the condensing purpose. Another vessel serves to receive the condensed liquid. A similar arrangement of tubes and vessels is placed at the other extremity of the apparatus, the tubes serving to carry off the water which has condensed or cooled the liquid, and the vessels to receive the fluid to be condensed and to distribute it between the surfaces of the copper plates. *Patent abandoned.*

2618. H. H. HIXSON. *Improvements in waterproofing fabrics or materials.* Dated November 19, 1858.

This relates to a former patent, and consists in the use in connection with any fabric treated with adhesive materials of solutions of chloride of zinc, a mixture of solutions of hydrated protoxide of lead, and sulphate or acetate of alumina, or both, or any soluble salt of alumina, or a mixture of a solution of silicate of soda, or silicate of potash and hydrated oxide of lead, or a mixture of solutions of nitrate of lead, acetate of lead, and sulphate of alumina, or soda, alum, manganese, or any of the double sulphates, or the elements or equivalents thereof, for rendering fabrics surface water-proof by immersion, pressure, or exhaustion. *Patent completed.*

2619. W. RAMSAR and J. G. SCOTT. *Improvements in fire-arms.* Dated November 19, 1858.

Here the patentees bore the breech end of the barrel so as to admit a metal cap for holding the charge, or to admit any prepared cartridge having its exterior of the same size and shape as the metal case, which latter is furnished with a nipple for percussion caps, and the cartridge with a pin communicating with the explosive compound. Or they make the breech of the same diameter as the barrel, without any recess, so that the cartridge may go with the charge. The case or cartridge is kept in its place by a drop-lid turning upon a joint at the side, and held when required by a locker. In the lid there is a movable plug furnished with a spring, one end of the plug corresponding with the nipple, or pin, and the other with the hammer. They raise the lid by hand, or cause it to be acted upon by one or more springs, so that it may be lifted immediately after the piece has been fired. When the piece is at full cock, and the drop-lid pulled back, the case or cartridge can be placed in or withdrawn from the recess with great facility. When the charged case with its nipple, covered with a cap, is placed in the recess, and the drop-lid locked, the piece is ready for firing, the hammer striking the plug, which acts on the percussion cap, or upon the pin when the prepared cartridge is used instead of the case. *Patent completed.*

2620. E. A. PONTIFEX. *Improvements in external surface condensers.* Dated Nov. 19, 1858.

This consists in fixing the transverse tubes in surface condensers at one end only, and in uniting the tubes to the

steam passages or chambers by means of yielding or expandable joints. *Patent completed.*

2621. H. BAILLY. *Improvements in heating razors.* Dated Nov. 19, 1858.

This consists in inserting the razors in a tube, in which the heat of a small night-light or flame passes when they are to be heated for shaving. *Patent completed.*

2622. W. CLARK. *Improvements in purifying natural phosphates of lime.* (A communication.) Dated Nov. 19, 1858.

This relates to a former patent, dated 25th Sept., 1858. For quickening the decomposition of the carbonate of lime, instead of utilizing the action only of but one chemical affinity, two chemical affinities are here developed, which act in the same manner for producing a similar decomposition of carbonate of lime. *Patent completed.*

2623. A. FELTON. *Improvements in fastening buttons and studs to dress and other articles.* Dated Nov. 19, 1858.

This consists in securing the buttons, studs, &c., by a hollow stem projected through the substance to which it is to be fastened, and the edge turned down and spread out in the form of a lip or flange, and in the manner of forming eyelets. *Patent abandoned.*

2624. J. E. F. LUCKEKE. *Improvements in motive power-engines.* Dated Nov. 19, 1858.

Here the inventor employs the power of magnetism to sustain a column or columns of fluid in a chamber or chamber, and above its natural level in a reservoir below. *Patent abandoned.*

2625. W. MAUSHALL. *Improvements in steam engines.* Dated Nov. 19, 1858.

According to this invention, as applied for marine purposes in screw propelling, each engine consists of a large and small inverted steam cylinder disposed in line athwart ship. The larger cylinder is inverted upon the top of an open supporting frame, the connecting rod working down direct to the crank or screw propeller shaft. To the piston rod joint there is also connected the inner end of a horizontal lever working upon a fixed centre, the other end of such lever being jointed to the top of a connecting rod working the air-pump bucket or piston. The air pump is disposed on the engine sole plate, or foundation to one side of the keel line of the ship, and directly above it is placed the small inverted steam cylinder carried on a suitable open frame or pedestal. The piston rod of this smaller cylinder is connected to the air-pump lever beneath, so that the piston moves in concert with the air-pump bucket. The steam at its normal pressure is primarily supplied to the smaller or high-pressure steam cylinder, and it is then exported into the larger one in the usual manner of double-cylinder expansive engines. There are modifications included. *Patent completed.*

2626. J. H. JOHNSON. *Improvements in the construction of telegraph cables or conductors.* (A communication.) Dated Nov. 19, 1858.

This consists in covering the conductors with plated, braided, or interwoven strands of hemp, flax, &c. *Patent completed.*

2627. A. J. THORMAN. *Improvements in chain cables and chains.* Dated November 19, 1858.

This invention is not described apart from the drawings. *Patent completed.*

2628. J. EASTON, sen., and C. E. AMOS. *Improved apparatus applicable to drains, sewers, and water-conduits for the purpose of removing extraneous solid matters therefrom.* Dated November 19, 1858.

This invention was described at page 363, No. 23 of the MECHANICS' MAGAZINE (New Series). *Patent completed.*

2629. A. V. NEWTON. *Improved apparatus for transmitting motive power.* (A communication.) Dated Nov. 19, 1858.

This relates to the use of a peculiar arrangement of balance or fly-wheel and cranks for transmitting motion in machinery, and rendering the momentum of the fly-wheel more effective in carrying the cranks past their dead points than when a wheel is applied in the ordinary manner in combination with cranks, whereby, in connection with the use of a load at one point in the periphery of the wheel, the centrifugal force generated in the wheel is rendered available as motive power. The invention is not described apart from the drawings. *Patent completed.*

2630. T. S. CHESSEY. *Improvements in machinery used in the manufacture of casks.* Dated Nov. 19, 1858.

To cut the edges of a stave to the proper curve and bevil, a circular saw-bench is used, on which a bar is fixed longitudinally, and to this bar is applied a flexible template of steel by screws and nuts, so as to admit of the flexible template being varied in its curvature to suit the size and make of cask desired. The wood for making a stave is fixed on a carriage, which is caused to move past the circular saw. This carriage has an arm at each end, to each of which a roller or truck is applied, which comes against the flexible template as the carriage is moved past the circular saw. The upper surface of the carriage is hinged at its inner edge to the bed-plate or frame of the carriage so that it may be made to assume an inclined position according to the degree of bevil desired to be given to the edge of a stave, and the degree of inclination of the upper surface of the carriage is adjusted by a wedge-formed gauge, which is graduated for different sizes of casks; and according as such gauge is passed more or less under the upper surface of the carriage in which the wood for a stave is fixed, so will be the degree of bevil produced on the wood when it has been moved past the circular saw. The wood is held in the upper surface of the carriage by its ends in any suitable way, and it is correctly placed in the carriage by the aid of an adjustable stop or stops on the saw-bench, and a spring and adjusting frame on the upper surface of the carriage. *Patent completed.*

2631. R. WARRY. *Loading cannon at the breech.* Dated Nov. 20, 1858.

Here the cannon is cast solid and bored from muzzle to breech through the caseable. Midway between the caseable and trunnions is a conical cylindrical plug or tumbler which is fastened to the left side of the gun by a steel

plate, through which and the whole breech of the gun this tumbler revolves, having a quarter turn by means of a lever; the shoulder and screw inside prevent it moving to either side. It has an angle protruding through the steel plate to which the lever is affixed; the quarter turn will either bring up the hollow side of the tumbler, which then forms and has all the resisting power of a breech, or leave the gun entirely open. The charge is introduced by the hand, and then placed beyond the tumbler by a flanged ramrod; this completed, the lever in the act of shutting the breech has also the power of cutting the cartridge end by means of the tumbler, and introduces the powder to the nipple, which is placed above the breech on the right hand side. The screw in the steel plate has the effect of easing the revolution of the tumbler, as in the opening of the gun it brings the tumbler slightly out of its bedding from right to left, which in shutting the tumbler it wholly recovers, thereby ensuring the tightness of the tumbler or breech during explosion. An oil hole is introduced at the left rear corner of the breech from the surface, for oiling the tumbler on the bottom side, and which prevents friction and assists in loading. The whole breech of the gun from the trunnions is square-shouldered outside. The bore from osacle to the length of the charge in front of the tumbler is a shade larger than the bore of the fore-reach of the gun to admit the charge easily. *Patent abandoned.*

2632. J. WADSWORTH. Improvements in gas-burners, and in the means or methods of, and in apparatus for, moderating, or retarding, or governing the flow and pressure of gas used for illumination, and in street lamps or lanterns for shielding flame from the action of wind and rain. Dated Nov. 20, 1858.

This consists in constructing an apparatus so that the current of gas before issuing from the burner may have its velocity retarded by passing through a tortuous passage. It consists also in the use for retarding the velocity of the gas, of a button or mushroom-shaped stud or deflector, supported only by its stalk or central stem, and not touching the internal surface of the pipe or cavity which contains it. It also consists in the use of the said button or mushroom-shaped deflector as a substitute for a small disc or plate of metal placed transversely across, and dividing an expansion chamber used for rarefying and expanding the gas, and for raising the temperature thereof. *Patent completed.*

2633. C. F. VASSEKOT. Improvements in fire-arms and ordnance, and in the projectiles to be used therewith. (A communication.) Dated November 20, 1858.

This method of constructing cannon consists in, 1. a base of cast iron, steel, or wrought iron. 2. A case of metal composition composed of 90 parts copper, 9 parts tin, and 1 part lead, cast round the base. 3. Two or more layers of bands or hoops of wrought iron enclosing the above united metals. The hoops are formed with a male and female screw, and screw one into the other so as to form a perfect cylinder; they are put on to the gun when expanded by heat. *Patent completed.*

2634. D. BOWAN and S. ROBERTSON. Improvements in steam engines. Dated November 20, 1858.

An engine, or a set of engines, constructed according to a portion of this invention comprises one or more duplex cylinders. Each duplex cylinder consists of an outer annular cylinder combined with a central cylinder or cylindrical space. Pistons working in the central and annular cylinders are connected by their piston rods to a cross head, or to the crank shaft, in such way as to work together. According to one modification the supply of steam to the cylinders is governed by a valve or valves so that the steam from the boiler first enters the central cylinder, next passes thence to the opposite end of the annular cylinder, and finally passes from the annular cylinder into the condenser. Another portion of the invention relates to an arrangement of valvular mechanism specially designed for application to the duplex cylinders, but also applicable to other double-cylinder expansive engines. There are several modifications included. *Patent abandoned.*

2635. H. ELLIS. Improvements in machinery or apparatus for cultivating, cleaning, and pulverizing land. Dated November 20, 1858.

This consists of a wood or iron frame mounted upon a pair of large wheels the tyres of which are provided with movable teeth or spikes, which are to be taken out when the apparatus is travelling along roads, and inserted when in use on the land for increasing the bite of the wheels. A pair of ordinary draught shafts are fitted to the frame, and the whole drawn by horses; or it may be adapted for traction by steam power. The actual cultivator consists of one or more cylinders fitted with curved spikes and carried in a vibrating frame centred so as to work freely on the main axle as a fulcrum. Suspending chains are connected to the after end of the vibrating frame, and are passed over an overhead roller fitted with a ratchet wheel and detent apparatus and cross arms for elevating the cylinders. A rotary motion is imparted to the cylinders from the running wheels by toothed gearing. *Patent completed.*

2636. C. TOMLINSON. Improvements in stop taps or valves. Dated November 20, 1858.

This relates to valves or taps which close by the motion of a valve or plug which is bedded in or removed from its seating, and which is arranged so that the valve or plug opens against the pressure of the fluid the supply of which is to be regulated. That this valve or plug may be removed when required without opening the passage for the fluid the patentee fits another similar valve in combination with the first mentioned, so that it stops the passage when the primary valve is closed, as also when it is removed from its seating. *Patent completed.*

2637. C. CURT. Improvements in railway brakes. Dated November 20, 1858.

This brake is formed of two lever or hollow beams between which the wheels of the vehicle rotate. These beams are united by transverse pieces, forming together with the beams a frame of four sides suspended by rods or chains joined to the framework of the carriage. This frame is

worked by a winch, &c., actuated by the guard, who, when wishing to stop the carriage, lowers the brake frame on the rails so that the beams descend on the rails, and travel thereon on rollers, or small wheels fitted thereto, which are furnished with flanges, and turn on double axles in the beams. When the frame thus rests on the rails its movement of descent brings a number of inclined planes under the wheels of the carriage on which the wheels mount, and so raise the said carriage. The carriage suspended thus on the frame will be rolled on the rail, and stops without shock. *Patent completed.*

2638. W. LEA. A method of lubricating cocks and taps. Dated November 20, 1858.

This consists in lubricating the plugs both above and below, or either above and below the liquid way through one or more apertures made in the barrel above and below the liquid way, or either above or below it, which apertures open into a reservoir formed on the outside of the barrel, which reservoir is to be kept supplied with oil, or other lubricating material, and is closed at top by a screw, or other stopper. *Patent completed.*

2639. R. A. BROOMAN. Improvements in the manufacture of dolls, statuettes, figures of animals, and others, and toys. (A communication.) Dated November 20, 1858.

This consists in forming dolls and other figures in vulcanized caoutchouc, as follows:—A metal mould of the object to be formed is suitably prepared, and a hermetically closed ball of caoutchouc is placed in the mould, and the parts thereof locked. Thus prepared, the mould is plunged into the hot vulcanising composition. During this operation the air inside the caoutchouc ball is expanded by the heat, and forces the caoutchouc against and into the sides of the mould, and makes it assume the interior shape and form thereof, which form it will preserve after being removed from the mould. It also consists in forming different parts of the figure in separate moulds, and in inserting articulated, wooden, or metal limbs, with the joints placed so as to allow the figure to bend at the knees, elbows, &c. *Patent abandoned.*

PROVISIONAL PROTECTIONS.

Dated March 18, 1859.

686. F. Potts, Tube Manufacturer, of Birmingham. A combined metallic support and label for training, supporting, removing, and transplanting flowers or trees, in gardens or green or hothouses or for other horticultural purposes.

Dated May 31, 1859.

1339. W. Smith, of Salisbury-street, Adelphi. Apparatus for raising and docking ships, and other similar purposes. A communication from J. W. Nyström.

Dated June 1, 1859.

1350. G. H. and H. R. Cottam, of Old Saint Pancras-road. Improvements in stable fittings.

Dated June 6, 1859.

1381. T. Hyland, of Manchester, Manufacturing Chemist. Improvements in the manufacture of gum or dextrine, and their compounds, from starch.

1383. J. Ferrabee, of Stroud, Engineer. Improved machinery for forming bats of fleece or sheet silver, and also for folding cloth and other fabrics.

Dated June 7, 1859.

1385. C. Pooley, of Manchester, Cotton Spinner. Improvements in machinery for preparing to spin, and for spinning cotton and other fibrous materials.

1387. P. Salmon, of Glasgow, Merchant. Improvements in valves for pumps and other uses.

1389. W. H. Dorman, of Old Broad-st., and C. Cowper, of Southampton-buildings. Improvements in traction and locomotive engines.

1391. J. Greenfield, of Oxford. Improvements in fastenings for dresses and other like apparel.

1393. F. Muir, of Paisley, Pattern Printer. Improvements in ornamental or colour printing.

Dated June 8, 1859.

1395. C. de Berge, of Dowgate-hill, Engineer. Improvements in machinery for punching and shearing metal. Partly a communication from M. de Berge.

1397. J. N. Royer, Tailor, of Paris. Improvements in the manufacture of wadded or quilted fabrics, and in their limitation.

1399. C. W. Eddy, of Kegworth, Leicester, Master of Arts. An improvement in reaping machines.

1401. J. E. Ashby, of Enfield, Bachelor of Arts. Improvements in sights for fire-arms.

Dated June 9, 1859.

1403. G. Bartholomew, of Linlithgow, Edge Tool Maker. Improvements in shoes for horses and other animals.

1404. J. H. Tuck, of Great George-street, Westminster. Improvements in breakwaters, sea walls, and like structures.

1405. E. Welsford, of Bona, Algeria, Proprietor. Improvements in tanning.

Dated June 10, 1859.

1406. T. Greenhalghs, of Little Titchfield-st. Improvements in purifying gas and obtaining ammoniacal and other salts.

1407. M. J. Haines, of Dursley, Strap Maker. Improvements in the manufacture of driving straps or bands.

1408. G. J. Farmer, of Birmingham, Machinist, and G. B. Hardy, of Brompton, Chemist. Improvements in stair rods and eyes or sockets, which are also applicable for other purposes.

1409. A. F. Haas, of Camomile-st., Merchant. Improvements in lamp and gas shades or glasses.

1410. F. Fuls, Chemist, of Haverstock-hill. Improvements in the treatment of hydro-carbons.

1411. S. W. Tyler, of Greenwich, New York. Improvements in harvesters.

1412. W. Sellers, of Philadelphia, Engineer. Improvements in ovens for baking bread or other substances, which improvements are also applicable for drying, annealing, and other analogous purposes.

1413. M. H. Picciotto, of Finsbury-circus, Merchant. Improvements in apparatus for producing or obtaining motive power.

Dated June 11, 1859.

1414. W. Donbavand, of Manchester, Scale-beam Maker, and D. Crichton, of the same place, Machinist. Improvements in looms for weaving.

1415. J. James, of Lambeth, Engineer. Improvements in obtaining and applying motive power.

1416. F. Palling, of Lambeth, Clerk. Improvements in the construction of lamps for the purpose of burning tallow, grease, or oils, either singly or in combination.

1417. T. F. Henley, of Pimlico. Improvements in obtaining alcohol or spirit from rice and other grain, and in apparatus for that purpose.

1418. H. J. Nicoll, Merchant Tailor, of Regent-st. Improvements in trowers.

1419. A. V. Newton, of Chancery-lane. An improvement in fire-arms. A communication from C. T. Pierson.

1420. F. A. R. de Beauregard, of Paris, Civil Engineer. Certain improvements in generating steam, and in apparatus for obtaining power and in generating steam for other purposes.

1421. G. C. Ash, of Hampstead. Improvements in the manufacture of artificial teeth.

Dated June 13, 1859.

1422. B. Baugh, of Birmingham, manager. Certain improvements in apparatus or machinery for raising metals.

1423. H. L. Corlett, of Inchicore, Dublin, Engineer. Improvements in rails, and the permanent way of railways, parts of such improvements being applicable to common roads.

1424. O. Maggs, of Bourton, Dorset. Improvements in washing machines.

1425. A. Smith, of Brixton. Improvements in bleaching and purifying bees' wax.

1426. C. N. Kottula, of Liverpool, Soap Manufacturer. A means of cleansing or purifying the "Thames."

1427. J. T. Smets, of Placamen, France, Distiller. Improvements in the manufacture of vinegar from grain and other vegetable products containing saccharine matter, and from a refuse product obtained in the manufacture of starch; also in apparatuses employed therein.

1428. A. V. Newton, of Chancery-lane. Improvements in the fitting of life and other boats. A communication from M. Ludlum.

1429. W. E. Newton, of Chancery-lane. Improvements in the manufacture of piled fabrics, and in the machinery employed in such manufacture. A communication from C. Miller.

Dated June 14, 1859.

1430. G. Smith, of Newington. Improvements in hat-bands.

1431. W. Brown, jun., of Selkirk, Manufacturer, and S. Bathgate, of the same place, Engineer. Improvements in machinery or apparatus for carding and treating or preparing fibrous materials.

1432. J. Dixon, of Bishopwearmouth, Durham, Engineer. Improvements in puddling steel.

1433. J. Cowan, of Barnes, Soap Manufacturer. An improved soap.

1434. J. Wansbrough, of Bridge-st., Southwark, Manufacturer, and A. Bain, of Clerkenwell-green, Telegraph Engineer. Improvements in effecting communications between parts of railway trains.

1435. A. MacDonald, of Manchester, Engineer. Certain improvements in machinery or apparatus for punching patterns or devices upon metallic printing rollers or cylinders.

Dated June 15, 1859.

1436. E. J. Maumencé, Professor of Chemistry, and V. Rogelet, Merchant, of Reims, France. Using the "suint," or the portion soluble in water of the greasy substance found on the skin and hair of sheep for the purpose of manufacturing potash and other products.

1437. A. V. Newton, of Chancery-lane. Improvements in the manufacture of polishing wheels, sticks, and tools. A communication from T. J. Mayall.

Dated June 16, 1859.

1439. J. Taylor, of Aberdeon, Joiner. Improvements in planes or cutting tools for working in wood.

1440. S. Levy, of Manchester, Cap Manufacturer. Improvements in hats, caps, or coverings for the head.

1441. E. T. Hughes, of Chancery-lane. An improved night-lamp clock. A communication from L. Montanari.

1442. J. Luis, of Welbeck-st. A new syphon meter for liquids. A communication from A. Grenet.

1443. J. Luis, of Welbeck-street. An apparatus for regulating individually the pressure, expenditure, and light in gas burners. A communication from E. Ferguson.

1445. W. Birkmyre, of Port Glasgow, Manufacturer. Improvements in drying, treating, and preparing yarns or thread.

1447. C. H. Waring, of Neath Abbey, Glamorgan, Mining Engineer. Improvements in safety lamps.

1448. C. Wilkinson, of Slaithwaite, York, Merchant. Improvements in doubling or twisting silk, cotton, worsted, linen, or woollen yarns, or yarns from any other fibrous substance.

1449. T. E. Tallent, of Southwark-bridge-road, Engineer. Improvements in the manufacture of leather, and in machinery for that purpose.

1452. H. F. Smith, of Manchester, Agent. Improvements in the manufacture of driving straps or bands.

1454. A. V. Newton, of Chancery-lane. Improvements in casting cylinders and tubes. A communication from F. Adams.

1455. J. Harmer, of Brighton, Gentleman, and W. Parsons, of the same place. Improvements in fire-arms.

1456. T. Cattell, of Euston-sq., Doctor of Medicine. Improvements in the manufacture of varnish and lacker.

Dated June 17, 1859.

1457. T. Orrell, jun., of Bolton-le-Moors, Cotton Spinner. Certain improvements in mules for spinning.

1458. H. Evette, of Lisleux, France, Manufacturer. A new system of bedding.

1459. E. T. Hughes, of Chancery-lane. Improvements in treating and decomposing fatty substances. A communication from C. Leroy and J. J. M. Durand.

1460. W. H. Hammersley, of Leek, Silk Dyer. Improvements in stringing, glossing, or finishing silk, and apparatus employed therein. A communication from J. Leigh.

1461. D. Deas, of Carnell, Fife, Farmer. Improvements in reaping machines.

1462. R. A. Brooman, of 166 Fleet-st., London, Patent Agent. Improvements in generating anhydrous steam, and in apparatus employed therein and connected therewith. A communication from C. M. C. Duplay.

1463. C. F. Vassero, of Essex-st., Strand. Improvements in the construction of stereoscopes. A communication from H. A. Corbin.

1464. J. J. L. Guiblet, of Wilmington-sq. Improvements in watches.

1465. A. V. Newton, of Chancery-lane. Improved means for assorting substances of different specific gravities. A communication from D. Marchal.

1466. J. Combe, of Leeds, Engineer, and R. Smalpage, of the same place, Woollen Draper. Improvements in winding and spinning machinery, and in arranging and securing a uniform delivery from cops, to be used as woff or warp or for other purposes.

PATENTS APPLIED FOR WITH COMPLETE SPECIFICATIONS.

1444. L. Barroux, of Paris. A new system of rail-road, supported on iron soles, with or without wood being used. Dated June 16, 1859.

1451. M. A. F. Menmons, of Paris. An improved kiln for brick and plaster burning. A communication from A. Mombun. Dated June 16, 1859.

1453. E. A. Cutler, of Connecticut. A new and useful machine for making horse-shoes. A communication from C. H. Perkins. Dated June 16, 1859.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

(From the London Gazette, June 28, 1859.)

154. J. Fawcett. Food for cattle.
 420. W. Raymond. Life-raft.
 421. J. Paterson. Bruce buckles, loops, and braces.
 428. C. E. Wright. Nursing infants.
 441. S. T. Cooper. Artificial light.
 447. F. W. Emerson. Treating ores of lead.
 449. J. H. Johnson. Propelling and steering. A communication.
 465. C. F. Vassero. Carding machines. A communication.
 467. F. P. J. Van den Ouwelant. Fire-places.
 471. T. Wilson. Ordnance.
 474. P. Spence. Alum.
 475. R. Jobson. Lubricating bearings.
 484. J. Hine. Book-slide.
 486. R. A. Brooman. Fixing tannin; dyeing. A communication.
 490. S. Ridge. Joints of pipes.
 500. H. Mushet. Metallic compound.
 501. R. Mushet. Cast steel.
 504. A. Lancon, jun. Watches.
 512. C. W. Siemens. Telegraphs. Partly a communication.
 513. W. McNaught. Steam-engines.
 520. J. Lee. Ploughs.
 523. E. Gatwood. Springs.
 525. A. Martin. Weaving.
 536. E. J. Hughes. Preserving food. A communication.
 539. H. Moule. Evaporating, &c.
 553. J. W. Harker and J. K. Field. Coating vessels. A communication.
 604. C. Mills. Pianofortes.
 618. W. E. Newton. Billiard tables. A communication.
 693. C. Lambert. Seed drills.
 704. W. and S. Pickstone. Textile fabrics.
 768. M. A. Muir. Moulding metals.
 1008. J. Childs. Night-light cases.
 1143. W. S. Booth. Washing machine.
 1156. W. Jeffery. Tent camera.
 1189. D. Foxwell. Sewing machines.
 1258. T. S. Cressey. Cutting staves.
 1288. D. S. Price. Dyeing and printing.
 1291. A. Prince. Ships. A communication.
 1292. A. Prince. Propellers. A communication.
 1302. J. Young. Locks, &c.
 1333. I. and R. Blackburn. Traction engines.
 1374. R. Chimes. Urinals, wash-hand basins, &c.
 1375. E. Gill. Producing spirit.
 1336. J. B. Howell, J. Hick, and W. Hargreaves. Applying heat; combustion of smoke.
 1400. A. V. Newton. Gas meters. A communication.
 1413. M. H. Picciotto. Motive power.
 1415. J. James. Motive power.
 1431. W. Brown, jun. Carding fibrous materials.
 1451. M. A. F. Menmons. Kiln. A communication.
 1453. E. A. Cutler. Horse shoes. A communication.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed June 24, 1859.

2939. J. T. P. Newbon, T. Smith, and J. Brown.	77. J. White.
2945. D. Edleston.	91. W. and W. T. G. Bray.
2952. W. B. Johnson.	108. H. Critchley and S. Elston.
2955. T. Steven and T. Scott.	129. W. H. E. McKnight.
2959. J. Macpherson.	139. P. A. S. S. Sicard.
2960. J. Davies.	142. E. Brooks.
2962. F. W. Turner.	167. J. H. Johnson.
2965. B. Browne.	201. D. Moseley.
2971. J. H. Johnson.	367. J. H. Johnson.
2992. J. H. Johnson.	518. F. Weeks.
3000. H. Robin.	715. G. Gregg.
1. J. T. Pitman.	757. J. H. Johnson.
7. J. Oliver.	1003. J. Allison.
23. J. B. Morgan.	1016. J. Armstrong.
7. J. Luis.	1074. A. Boyle.
70. W. E. Newton.	

Sealed June 28, 1859.

2976. R. D. Kay.	145. R. Mushet.
2989. R. A. Brooman.	175. T. Greenwood and J. Batley.
2990. R. A. Brooman.	178. T. Greenwood, J. Batley, and J. Dockray.
2991. R. A. Brooman.	182. H. Sagar and A. Schultz.
2992. R. A. Brooman.	183. T. Richardson.
2994. W. Burgess.	193. J. Childs.
2996. J. Knowelden and R. D. Edwards.	223. J. H. Johnson.
3003. F. W. A. Casper and G. H. Schmah.	262. H. Watson.
3006. L. A. Normandy, jun.	269. H. Grissell.
4. B. J. Gosteaun.	293. W. E. Newton.
5. J. E. Dromot.	509. A. Reid and R. Tonge.
9. J. Garforth.	845. D. B. White.
14. M. Wiggell.	951. H. A. Silver.
22. A. L. Lévéque.	996. H. Rawson.
81. J. Biers, jun.	1073. W. A. Tompson.
98. W. and W. McNaught.	1119. W. E. Newton.

PATENTS ON WHICH THE THIRD YEAR'S STAMP DUTY HAS BEEN PAID.

1468. G. Gurney.	1501. G. Durrich.
1471. G. Riley.	1513. A. Shanks.
1477. E. Hardon and J. Henry.	1526. C. A. Messenger-Abit.
1495. R. W. Chandler and T. Oliver.	1529. T. F. Healey.

NOTE.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennett Woodcroft, Great Seal Patent Office.

LIST OF MISCELLANEOUS TENDERS INVITED, AND ENGAGEMENTS OPEN.

The tenders and vacancies which appear in this weekly list are not repeated in succeeding numbers.

BRITISH IRON, East India Company.—Particulars at the Secretariat office, where the proposals are to be left before 11 forenoon, July 5.

GAS PIPES, Bilston Gas Company.—Cast iron, spigot, and socket pipes, as follows:—2,250 yards 8-in. pipes, weight per yard, 128 lbs.; 750 pipes; 780 yards 5-in. pipes, weight per yard, 70 lbs.; 260 pipes. Of an equal thickness throughout and sound, under 250 lbs. to the inch. Further information Mr. John Mudie, Resident Engineer, the Works, Moxley, Wednesbury. Tenders stating price per ton, July 14.

CAISSON, Leith.—For the entrance to the graving dock. Drawings, &c., Mr. Robertson, Resident Engineer, Dock Works, Leith. Tenders to John Phin, Clerk to the Commission, 13 Herod's Row, Edinburgh, July 16.

SEWERS, Mile End Old Town.—For the construction of sewers in certain streets in the east ward of the hamlet. Drawings with the Surveyor at the Town House. Tenders, with names of two sureties of £300, before 3 o'clock July 6, to Thos. Price, Clerk to the Vestry.

SEWERAGE WORKS, Harrington.—Contracts, 8 and 9. Drawings, &c., Mr. B. P. Coxon, borough engineer. Separate tenders, July 13, to chairman of Paving and Sewerage Committee.

BARRACK WORKS, Chatham.—1. Stripping, repairing, and slating 5 roofs at the carriage store, Gun-wharf, Chatham. 2. Erecting tower and water tank at Brompton Barracks, Chatham. Information, Royal Engineers' office, Chatham Lines, Kent. Tenders, July 9.

WORKHOUSE, Machynlleth.—Whole or portion of new workhouse. Drawings, &c., board-room. Bills, Mr. J. E. Oates, architect, York. Tenders, July 6.

CITADEL, Dover.—Extensive excavations in and raising the parapets of the citadel. Information Royal Engineer's Office, Dover, July 5. No date given.

GASHOLDER, Gateshead.—100 ft. diameter, 30 ft. deep. Specifications Mr. J. Bourne, engineer, of North Eastern Railway, Central Station, Newcastle-upon-Tyne. July 6.

ROADS, Norwood.—For the excavations, earthwork, drains, and culvert required in the formation and metalling of roads to be formed on the White Horse estate, Norwood. Drawings, &c., Messrs. Burrell, Surveyors, 14 Lincoln's Inn Fields. July 5.

CEMETERY, Walcot, Salop.—For chapels, lodge, entrance gates and boundary walls. Drawings, &c., Messrs. Dickes and Isaacs, 13 Northgate-street, Bath. Tenders July 11.

WORKHOUSE, East Grinstead, Sussex.—Drawings, &c., Mr. S. F. Cox, 22 Henrietta-street, Covent Garden; of whom and of Mr. W. Lase, further particulars. Tenders 1 o'clock July 7.

PASSAGE HOUSE, Nantygw, Newport, Monmouthshire.—Plans, &c., Rev. J. Morgan, Nantygw. Estimates to Mr. Norton, 41 Old Bond-street, London, July 9.

FARM HOUSE, &c., Horsham-park Estate, Sussex.—Plans, &c., Kingshead, Horsham. Tenders, July 5.

HOUSES, Bishop Canning's Estate, Wiltshire.—Erection of cottages, farm premises, and alterations and repairs at farms. Plans, Crown Inn, Bishop's Canning's. July 4.

FARM HOUSE, &c., Earnhill Estate, Somerset.—Plans, &c., Mr. Hilliers, Donyatt, near Ilminster. July 9.

STONE, Leamington.—1,000 tons of the best hand-picked Hartshill, and 15 tons of Hartshill rough grouse for macadamizing, at the Tebbrook-road wharf, Leamington, in quantities, during the next three months. Tenders, the Surveyor, Town Hall, July 4.

DESIGNS FOR CEMETERY, Great Malvern.—Lithographed plan of the ground, and rules, of the Churchwardens. No date given.

FLINTS AND BROKEN GRANITE, Bethnal Green.—2,000 yards of picked Kent flints, broken to a two-inch gauge, at the vestry's wharf, Old Ford-road, pursuant to specifications of the surveyor, Town Hall. Tenders with a £10 note at the office of the vestry clerk, Town Hall, Bethnal Green, July 6. Also 2,000 yards of broken granite. Conditions and time for tenders same as for flints.

COAL, Pancras Workhouse.—500 tons of Lambton or Stewart's Wallsend, and 300 tons of good strong furnace. Tenders, 2 o'clock, July 12.

COAL, Tunbridge Wells Gas Company.—3,000 tons of Harvey Main gas, at per ton, in periodical deliveries. Tenders, 6 p.m., July 13.

COKE, London, Brighton, and South Coast.—For the supply of 3,000 tons of the best locomotive, to be delivered at their option alongside Deptford, Newhaven, or Kingston wharfs, near Shorham. Delivery to commence at once, in portions of not less than 300 nor more than 500 tons per month. A separate price to be quoted at each place. Quantities approved one month to be paid for in the next. Further particulars, Mr. J. C. Craven, Brighton terminus. Tenders by 10 A.M., July 7.

WORKING OF COKE OVENS, London, Brighton, and South Coast Railway.—The contractor to supply the coal and to keep the ovens in repair. The produce to be 213 tons per week. Ovens, New Cross. Term, 12 months, commencing August 1. At per ton, delivered into the wagons at the siding adjoining the ovens: to which siding the coal will be conveyed, free of charge to the contractor, from the Company's wharf at Deptford. Particulars, Mr. J. C. Craven, Brighton Terminus. Tenders, by 10 A.M., July 7.

SURVIVOR, &c., Aldershot.—To act as inspector of nuisances, and collector of rates also, for the parish of Aldershot. Salary, £50 per annum. Candidates to attend at the meeting of the Board of Health, Aldershot, at eleven, July 5.

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, JULY 8, 1859.

THE IRON STEAM FRIGATES OR
RAMS.

THE writer of an article which appeared in the *Times* of Thursday, the 30th ult., and was quoted in our last number, criticised the Admiralty with some severity, and not without sarcasm. The grounds of his complaints were, first, that a foolish attempt to conceal the character of the new iron ship in the presence of an enemy was contemplated; and, secondly, that while the great purpose with which the ship has been designed is that of "ramming" down an enemy, no provision has been made for clearing her of her masts and rigging—which must, the writer assumes, "come down" by the run, when the ship is driven against the enemy.

Now, offensive as it may be to show that the premises from which such weighty conclusions are drawn are false, we have to state that the writer in question is wrong in both his assumptions. No absurd attempt to conceal the character of the new ship from the enemy is contemplated. The only fact brought by the writer in support of his view—or rather, the only fact upon which his conclusion in this matter is based—is that the new ship, like every other large English ship of war, is to be furnished with a knee of the head. It may be true that this feature of the vessel will in her case be of less service than it ordinarily is, since the bowsprit and bowsprit rigging may possibly be fitted independently of it. But without such a feature the vessel would be needlessly ugly; and it is doubtless for this reason, if not for any other, that the knee is to be fitted. We do not—we cannot—for a single moment believe that the Admiralty authorities have connected any fatuous expectations of concealment from the enemy with their arrangements in this respect. It is evident that if the knee of the head were omitted from this particular ship that feature would be so "conspicuous by its absence" that her character would be declared at a glance to the dullest enemy, if he had but eyes in his head. This the Admiralty know, of course, perfectly well, and are too prudent to give so conspicuous a sign to the foe. As they intend to build her, she may be so fortunate as to escape the observation of some careless observer at the right time, and this chance is accordingly given her. To say that the Admiralty anticipate more than this is to libel their intelligence.

In his second position the writer is equally at fault. The ship in question has been designed, not as a ram primarily, but as a shell-proof frigate. Her armament, and not her bow, is to be her means of offence. The Admiralty have very judiciously decided on so forming and strengthening her bow that if, upon an emergency, the resort to such a clumsy and questionable expedient as that of attacking a ship by running full butt against her should be deemed advisable, the operation may be effected with as little damage as possible to the new iron ship. And as Admiral Sartorius and Mr. Nasmyth have taken so much trouble to recommend this expedient to ourselves, the French, and others, no one can blame the Admiralty for the step they have taken in this respect. But it is altogether a mistake to suppose that the ram-bow is any more than a subordinate feature of the ship.

The *Times* writer deems it "unwise to cum-

ber her with the masts and rigging of a line-of-battle ship." We entirely dissent from him. Were she not so rigged it would be impossible to send her with safety in the presence of an enemy. Lighter masts and rigging would never afford her the necessary means of sailing and manœuvring in the event of her screw, her engines, or her fuel failing, and we know too little of the effects of a naval battle with steamships to leave such a ship dependent upon her steam alone. No action between steamships has yet been fought, and it is very doubtful if such an action would not reveal the impotence of either the screw or the engines in close conflict. Especially is this true now that rifled guns, and other weapons of precision, are finding their way into ships of war.

Nor can we leave this point without mentioning that the writer under notice has unwittingly dealt a heavy blow to the scheme of Admiral Sartorius. The question which the former has sarcastically put to the Admiralty really addresses itself to that gallant officer. How does he propose to clear his "ram" of her own wreck of masts and spars? This is for him to answer, because the running down of ships is the primary object of his vessel.

There are many minor inaccuracies in the article under notice, some of which it may be worth while to mention. The writer says:—

"Neither the bows nor stern have any of the large armour plates, but are coated with wrought iron plates of nearly one inch and a half thick over two feet of teak, which will offer sufficient resistance to prevent most shots from going through. But to compensate for this apparent deficiency both bows and stern are so crossed and recrossed in every direction with water-tight compartments that it is a matter of perfect indifference whether they get riddled or not, and each of these ends are shut off from the engine-room and fighting portion of the ship by continuous massive wrought iron transverse bulkheads. So that, supposing it possible that both stem and stern could be shot away, the centre of the vessel would remain complete and impenetrable as ever, still offering in all 24 inches of teak coated with 5 inches of wrought iron to every shot. But both stem and stern are built inside of such immense strength that coating with armour plates would be almost superfluous. The bows, as the spot where the whole shock must be received in running down ships, are inside a perfect web of ironwork, strengthened back to the armour plates with no less than eight wrought iron decks an inch thick, and crossed and recrossed in all ways and methods with diagonal bracings and supports."

All the passages marked in italics are entirely wrong. Neither the bow nor the stern is either coated with 1½ inch iron or lined with teak. They are, so far as the plans at present adopted provide, formed of iron similar to that used in ordinary stout iron ships. Nor are the bows and stern to be crossed and recrossed with water-tight compartments "in every direction." They have several flats of thin iron at different heights, corresponding to ordinary decks; but the only water-tight bulkheads are a few transverse ones of common iron. This is, of course, exclusive of the transverse shell-proof bulkheads at either end of the defended portion of the vessel. These are formed of 4½ in. (not 5 in.) iron backed with wood. The "diagonal bracings" and supports," spoken of by the writer, form no part of the Admiralty design, so far as that is yet completed. The same remark applies to the "telescopic bowsprit," mentioned elsewhere by him.

It is much to be regretted that the false impressions which such an article as that referred to must necessarily produce should have gone forth to the ends of the world with the sanction and authority of the *Times*. While so much room is afforded by the Admiralty for just and useful criticism, it is sad to see the power and influence of such a journal frittered away in such a manner.

THE DECIMAL SYSTEM.

THE question of a Decimal Scale, as regards weights and measures, is not by any means a novelty. In the year 1816 a Royal Commission was appointed "to consider how far it might be practicable or advisable to establish a more uniform system of weights and measures." The Commissioners were Sir Joseph Banks, Sir George Clerk, Mr. Davies Gilbert, Dr. Wollaston, Dr. Thomas Young, and Captain Kater. Three years subsequently, these gentlemen made their unanimous report, and it was adverse to alteration. In 1824 Sir John Wrottesley brought before the House of Commons a motion for inquiring into the applicability of the decimal scale to coins. He referred to the example of France, of America, and China, and urged the simplicity of their system of accounts as compared with the complex arrangements in use at home. Sir John's scheme was to employ pounds, double shillings, and farthings, the last having four per cent deducted from their present value, and thus making 100 farthings = 1 double shilling, 1,000 farthings = 10 double shillings = 1 pound. At that time of day it was customary for Masters of the Mint to have seats in the House of Commons, and Mr. Wallace, who then filled the office, opposed Sir John Wrottesley's plan, whilst admitting its advantages. The motion was unfortunately therefore withdrawn—the only good which came of it being that the Government agreed to assimilate the currencies of Great Britain and Ireland; a promise faithfully kept shortly after. Matters rested thus till 1834, when the Houses of Parliament were burnt, and the standards of weights and measures were destroyed in the fire. Much discussion followed this catastrophe—the destruction of the standards, we mean—and the question of their restoration was referred to a Commission in 1838. In 1841—three years appear to be the usual period for hatching a report—in 1841 this Commission, which included three astronomers, made their report; and it contained among other matters the following statement: "The first point which has called for our special notice is the general question of the decimal scale. In introducing this subject we invite the attention of Government to the advantage and the facility of establishing in this country a decimal system of coinage. In our opinion no single change which it is in the power of a Government to effect in our monetary system would be felt by all classes as equally beneficial with this." The worthy Commissioners then proceed to recommend substantially the plan of Sir John Wrottesley previously mentioned. The consequence of this recommendation was, that in 1843 another Commission was appointed with a view to a further consideration of the matter. The report of this Commission, which included Lord Wrottesley—formerly Sir John—proposed to carry out the suggestion of the standard Commission of 1841.

On the 27th April, 1847, Sir John Bowring moved for an address to the Crown in favour of the coinage of silver pieces of the value of 16th and 18th of the pound sterling. Sir Charles Wood, the Chancellor of the Exchequer of that day, objected to the latter coin but had no objection to the former—hence, Sir John Bowring, preferring a half measure to no measure at all, withdrew his motion—and the florin was ordained. A considerable period elapsed before the new coin made its appearance, and when it did so, it was amid great uproar. The engraver of the Mint, W. Wyon, Esq.—since deceased—had engraved several model dies for the new coin, and these, or rather pieces struck from them, had to be submitted to Her Majesty and Prince Albert for approval.

It did so happen that these illustrious personages fixed upon that peculiar design in which the artist had been compelled, from the small diameter of the die, to omit from the legend on the obverse the words *DEI GRATIA*, and even the initials D. G. Now arose the uproar, the Master of the Mint, poor Mr. Sheil, who had been appointed for the express purpose of ejecting from their posts the Company of Moneyers, and who was innocent of everything pertaining to coining—poor Mr. Sheil was a Roman Catholic, and several zealous Protestants, therefore, began to cry out—Conspiracy! Conspiracy! For had not the clever little lawyer eliminated that part of the inscription from the new coin which makes Her Majesty reign “by the Grace of God?” The hue and cry raised against Mr. Sheil and his “Godless” Florin—a wonder it was not named the “Devil’s ducat.”—added to the real disadvantage of the coin being too dumpy to be musical when thrown on a counter, led to the withdrawal, or rather to the discontinuance of the coining of the experimental piece; and Mr. Wyon engraved the dies for the existing florin, in which the theological difficulty and that of the shopkeeper are swept away. So much for the introduction of the first decimal coin. A very large issue of these $\frac{1}{10}$ ths of the pound had gone on up to 1853, when Mr. W. Brown, M.P. for South Lancashire, moved for a Select Committee—*Commissions* had, it seemed, done their best and worst—to take into consideration and report (once more) on the advantages or otherwise which would arise from adopting a decimal system of coinage. The Committee was appointed—all the witnesses examined by it, twenty-five in number, with the exception of Mr. Headlam, M.P. for Newcastle, were in favour of the introduction of the particular scheme proposed in 1841 and 1843, and known as the Pound and Mil scheme. In August, 1853, three months after its nomination, this comparatively hard-working Committee reported itself. The report stated that the existing system was needlessly complicated, calculated to create confusion as regarded questions of Foreign Exchanges, and otherwise generally inconvenient. By the introduction of the decimal system, on the contrary, the Committee’s report went on to assert, an important benefit would be derived in several departments of the public service and in every branch of industry, from the economy of skilled labour which would result from the proposed change; at the same time, that education in our schools, so far as arithmetic was concerned, would be facilitated. The Committee of 1853 further recommended the pound sterling as the unit of the new system of coinage—a recommendation which, at this hour, we think to have been based on a truthful foundation.

This unmistakable opinion, backed by a quarter of a hundred of scientific witnesses, when it came to be promulgated raised much discussion in pamphlets, newspapers, and magazines, and zealous advocates of the old and new schemes did battle on the occasion.

The year 1853 may be considered an era in the decimal coinage agitation, and early in 1854 a Decimal Association owing its rise principally to that agitation sprang into existence. A deputation from this active and persevering body soon waited upon Mr. Chancellor of the Exchequer Gladstone, and urged the immediate introduction of the Pound and Mil scheme. Mr. Gladstone met the proposition with some remarks which showed his knowledge of the subject, and leads us now to hope that, restored to the same onerous post he then occupied, there is still a chance, despite Lord Overstone, of a decimal coinage. Mr. Gladstone said he could not doubt

that a decimal system of coinage would be of immense advantage in monetary transactions. The weight of evidence was entirely irresistible on that point. As to the particular system to be most beneficially introduced, that was another thing. We had not anything like unanimity on that point. The Government could scarcely take the initiative, unless a definite plan calculated to overcome prejudice among the masses of the people generally and to meet business complications could be set before them. In such terms and by prescribing patience did Mr. Gladstone meet the deputation of 1854.

There is no doubt that since then the popular mind has been considerably enlightened on the matter, for fortunately the association named have by means of tracts, discussions, and lectures, disseminated much valuable information on the subject. Mr. Cardwell—also again in power—in reply to a deputation in 1854 from the indefatigable body named, said that there was no doubt at all about the value of a decimal system of coinage—all authorities of any weight were unanimous in support of it. Like Mr. Gladstone, however, Mr. Cardwell could only counsel patience. Five years have elapsed since then. Surely patience is now entitled to its reward. On the 12th of June, 1855, Mr. W. Brown moved the following resolutions in the House of Commons: 1. That in the opinion of this House the initiation of the decimal system by the issue of the florin has been eminently successful and satisfactory. 2. That a further extension of the system will be of public advantage. A long debate followed, and on a division the first resolution was carried by 135 to 56. The second resolution was carried without a division, whilst a third which advised a completion of the decimal scale by the issue of silver coins of the value of the 100th part of a pound, and copper pieces of the value of the 1000th of a pound, was withdrawn.

The Government objected during the debate so manfully incited by Mr. Brown, to a change which would, they said, so “deeply affect the poorer classes.” They also promised the “most careful consideration possible to the subject” in the future. In 1856 a new Royal Commission, consisting of Thomas Spring, Lord Monteagle of Brandon, Samuel Jones Lord Overstone, and John Gellibrand Hubbard, Esq., was nominated for the purpose of inquiring into the “expediency of introducing the principle of decimal division into the coinage of our United Kingdom.” Of the labours of this latest Commission and its final report we shall probably have something to say next week.

Five and twenty years ago a Master of the Mint alone caused the rejection of Sir John Wrottesley’s scheme; now the opinion of a Master of the Mint is not equally weighty with that of Samuel Jones Lord Overstone—as it seems.

THE EDUCATION OF MECHANICAL WORKMEN.

Who is to determine what mechanical workmen shall be taught? Not the untaught workmen themselves, for the value of knowledge is known only to those who possess it. Not mere schoolmen or professors, for none but he who understands a craft can judge what is fittest for the craftsman. Who, then, shall tell us what that knowledge is by which, and by which alone, the appetite of the intelligent and aspiring mechanic may wisely and healthily be satiated? The question is of immense importance in this land and this age; for our present energies seem directed almost exclusively to the development of mechanical agencies, and the extension of mechanical arts.

To us it appears plain enough that we must

look for enlightenment upon this subject to those few men who, while eminent for mechanical skill themselves, have the happiness to combine with it that sound sense and that liberal culture which are indispensable to every man who would guide the minds of others in these times. Perhaps there is no man more thoroughly competent to enlighten and advise us upon it than the gentleman who last month spoke upon this very question to the students and visitors at the South Kensington Museum—Mr. J. Scott Russell. If we had been asked to point to a person from whom the soundest knowledge of the intellectual wants and necessities of mechanical workmen might be elicited, to whom could we have more appropriately turned than to him whose brain and hand have for weeks past been, and at this very hour are, informing, directing, and controlling that huge hive of mechanics who are giving strength, and completeness, and splendour to that wonder of the modern world—the Great Eastern?

Mr. Russell’s lecture was undertaken in consequence of a conversation which took place not long ago between Mr. Henry Cole and himself on the subject of the education of the class of workmen to whom he (Mr. Russell), as he said, belonged. Mr. Cole had shown him some papers which he had prepared for the purpose of examining workmen as to the progress which they had made in the kind of education generally provided for them; and remarked that the education provided in this country for workmen was not very directly calculated to render them good workmen. With this Mr. Russell agreed, and as a large employer of skilled labour, he now (in his lecture) asked whether there was any description of education which would tend greatly to the increase of the skill, dexterity, ability, and success of the practical working mechanic. He maintained that there was, but that the mechanic did not get it. He himself was obliged to get his very best draughtsmen and mechanics from foreign countries. He had men in his employment from Prussia, Germany, and Holland; and he was bound to say that, as far as preliminary education was concerned, although the workmen of foreign countries had not the skill obtained by the British workmen from practical experience, their scientific knowledge was greater, and that knowledge was telling so rapidly on the present generation of workmen, that we were now equalled (he would not say excelled) by the workmen of many countries upon whom we were inclined to look down a few years ago.

This is strong and most serious testimony Mr. Russell did not say anything, of course, against the education now given. “On the contrary, he would say, continue to teach ‘drawing, reading, writing, and accounting in the best manner you can; but if you have a ‘class of young workmen coming forward to ‘learn, think how you can turn the little time ‘they can afford to give to the best advantage ‘so that you may raise them higher in the ‘social scale and make them better workmen.” In order to do this, it would be necessary to give them a higher class of education than they were ever taught before. We did not go far enough; but the pupil teachers whom he addressed were not to blame. The persons to blame were their teachers. Two years was perhaps all the time that could be devoted to education, and six months were often devoted to as many books of Euclid, which were wasted for all practical purposes, unless, indeed, the student intended to become a professor. He would advise them to skip over the beginning, and devote the least possible time to Euclid—in fact, he would advise them to do a very heterodox thing—to cut off all the propositions but the useful

ones. They might naturally exclaim, "Then how little will be left." Very little, he admitted, but plane trigonometry would be left. Suppose, for instance, a man had but six months in which to learn. Six weeks might in that case be given to Euclid, and then trigonometry might be commenced, solid geometry might next follow, and that constituted the whole education of the workman. But that was precisely what he did not get in the present day. He would also teach within the six months conic sections, and afterwards the nature of curves, within the first, second, third, and fourth degrees. He was aware he might be met by the exclamation, "Oh! but we shall be teaching them more than we ourselves understand;" but to this he would answer, "That is the fault of your education." Sir Isaac Newton discovered no less than 130 curves, and nine-tenths of them would be of great use to the mechanic, if he had them in two places—in his head and at his fingers' ends.

Having now got to teaching something which they did not know, and had not learned, the next thing they wanted was, said Mr. Russell, the assistance of the Government. Decent elementary text-books were wanted for the higher departments in mechanics, but there were many able men versed in the sciences; and what he wanted the Department of science and Art and the Government to do was, to ask the four cleverest men in England to write, in the fewest possible English words, all that they knew (not all that they had read), or, in fact, so much of their brains as they carried about with them. If Government would but pay handsomely for these books, a set of treatises might be collected such as the world never saw before, and such as would be sufficient to teach any mechanic his business. They might, it was true, say, "But we do not know where to get these clever men." But he knew where they were to be got. There were three of the four present at that moment; and if the Government would but give them a thousand pounds a-piece for writing the books, he was sure they would write them. What he had said about geometry was true as to mathematics. Of great importance to the working man was the comprehension of the laws and relations of numbers, so as to enable the working man to think in figures about the immediate business before him. Having explained the manner in which mechanics might make reduced or enlarged models, and the relations and practical properties of numbers, the lecturer illustrated the value of a knowledge on these points by an anecdote. "He remembered an instance in which a respectable working man sent in a tender for £12,500 for a very large piece of work. The tender appeared to be low, and he obtained the order, and got on some way with his work when he found he had made a trifling omission—he had forgot to multiply by two. His figures were all right, but in one place he forgot his multiplication, and his whole calculations were wrong." He was of opinion that geometry ought to be taught by a large and comprehensive system.

Mr. Russell continued to say that, with respect to solid geometry, the two great duties in a workman's life were conversion of materials and adaptation to strength. A mason who used up a wrong stone, or a carpenter who selected a wrong plank or piece of timber, showed that he was ignorant of one of the most useful portions of his art or calling. Now, nothing would teach conversion of materials like solid geometry; it was in fact the daily business of the workman. It had been said that every block of marble cut from the quarry contained a beautiful statue, but the art was how to get it out of it. This

was very true; for what workmen wanted to know was every shape, and how to get out another shape. The workman who took from a heap a block of stone, or piece of timber that cost his master 50s., when a piece could be got, answering quite as well, which cost 25s., inflicted a loss upon his employer perhaps equal to a week's wages. Hence the necessity of acquiring a knowledge of solid geometry. But if there were beauty in the quantity of numbers, and in regular geometrical figures, there was infinitely more beauty in curves. It was the duty of many mechanics, especially of those engaged in ship-building, to make curved lines. To him it had always been an interesting subject to learn how curves grew. He was aware that he might be told that the higher curves were never taught, but his answer was that they might easily be taught, and that they were very easy of comprehension. In order to effect this, somebody who understood the subject would have to be prevailed upon, not to write a book, but to put down in the shortest and plainest possible language what he knew of curves. This would be a treatise which the workmen could understand, and would be well worth the thousand pounds which he hoped the Government would be prevailed upon to give to one of the four clever men to write.

The remarks which we have above briefly sketched,* need no comment. It only remains for us to add the finishing words of the lecturer. The subject of the education of the workman was one which he had, he said, very much at heart. He did not know how it was to be given, but as the pupil teachers were present as an institution which took charge of the mechanic, and a Government which was anxious for the spread of education, he would urgently beg of them to take counsel with half-a-dozen of the best mathematicians of the day, and arrange with them to write short treatises, which could be circulated at a cheap rate, and which could be taught in our elementary schools. He also thought that there ought to be a large quantity of apparatus—a sort of inventory of education—of every conceivable shape and object. In addition to these models, he would have the schoolroom hung round, not with pictures of animals, but with solid bodies, which could be explained and drawn. He would, in fact, impart any kind of practical rather than book knowledge. If drawings merely were used instead of models, he did not think the student could imbibe so correct a notion of the object to be produced or delineated. There was a mode of studying forms called *la théorie de développement*, but the plain English meant nothing more than making flat surfaces into round and angular forms (as models now made from sheets of paper, which was a most valuable mode of studying forms). If this description of education could be given, he would take the pupils educated in that department and give them three guineas a week. He might afterwards raise them to foremen with salaries of £500 a year, and that would be far better than remaining all their lives at the bench, earning 30s. a week. Machinery could now be obtained to do all the unintellectual drudgery of mechanism. He was not opposed to machinery, and had no apprehension that it would supersede skilled intellectual handicraft. He would employ machinery to do all the drudgery that degraded the workman into a beast of burden. He would give him higher views of mathematics; he would show him that he was an intellectual, thinking being, with a soul for high and immortal things.

* From the only published report which we have seen, and which appeared first in the *Builder*, we believe.

A LORD ON LABOUR.

LORD NAPIER, our late representative in the United States, has, in his recent speech at the Society of Arts' dinner, addressed us on a topic of which it is cheering for us to be occasionally reminded. It cannot be too often repeated, said he, that more than half the population of the British empire live by arts, manufactures, and commerce—that is, they subsist on the results of skilled labour, or labour directed by speculation, invention, and design, in contradistinction to the simpler forms of industry. A vast proportion of the manufactured productions of the British people are exported to foreign countries, where they have to compete with the domestic manufactures of those countries, often guarded by protective tariffs, or with the productions of other states stimulated by commercial rivalry and administrative encouragement. Nor are the resources of the home market to be enjoyed in security or negligence; for though we possess in the unrivalled mineral structure of our soil a broad basis of natural advantages, and though we derive from the thrift and contrivance of our ancestors a noble heritage of accumulated capital and knowledge, yet we can only maintain our superiority by ceaseless vigilance and exertion, and we may not expect any artificial defence by a recurrence to the prohibitive system.

Starting with these considerations, he reminds us that the industrial movement of England at home and abroad is therefore one of anxiety and strife, and it is our bounden duty to levy from every department of intellectual inquiry auxiliaries in maintaining and enlarging our present ascendancy. "If we be true to the examples of the past and watchful of the present emergencies I would not speak with apprehension of our commercial future. Far from thinking that the universal demand has attained its full proportions, or that British industry has necessarily reached its culminating point, I conceive that the powers of consumption in the world never appeared so capable of indefinite expansion, and that the incalculable activity of another age may revert with curiosity, and perhaps with indulgence, to the respectable efforts of the nineteenth century. Passing over the home demand, which is susceptible of a steady development proportioned to the increasing numbers and wealth of the nation, there is much of an encouraging nature in the prospects of the foreign market, whether we regard those half-civilised nations which take off the commodities of common utility, or those communities at a higher stage of culture which afford a market for articles of luxury and beauty."

The ancient and stagnant empires of the East, recently disturbed by our diplomacy and arms, swarm, he tells us, with a population equal to the united numbers of Europe and America. Surely we are justified in expecting that the vehicles of our exchanges with those regions will not long continue to be silver and opium, the former of which owes no portion of its value to the manipulation of the British artizan, while the latter is the creature of monopoly and the cause of demoralisation. It is not extravagant to anticipate that when the barriers of traditional prejudice and fiscal exaction are dissolved, the multitudes of China and Japan will gradually unfold an immense market for the ordinary fabrics of Europe. Turkey, Persia, and Central Asia, without any important staple of exportation, and inhabited by a sparse, indigent, and in part vagrant population, approximately estimated at forty millions, annually absorb more than seven millions worth of British manufactures. At the same rate the inhabitants of the remoter East, who must eventually ex-

hibit greater faculties of consumption and exchange, would draw annually sixty millions' worth of goods from Great Britain—an amount equal to more than one half of the produce of the United Kingdom exported abroad. If Brazil be selected as the standard of comparison, a far higher result would be obtained. Add, then, to those portions of Asia but half appreciated and explored the nations of India, Africa, and the Pacific Archipelagos—all of which are, by conquest, commerce, or conversion, being subjugated to European ideas and manners—and the boundaries of our uncivilised market appear to recede into an impenetrable distance.

The aspirations of the British people are not limited, however, as the eloquent speaker reminds us, by the grosser conceptions of cheapness and quantity. It must not be alleged that the gracious genius of English industry merely drudges in the service of a barbarous demand. It is our aim to invest the most familiar and useful objects of manufacture with some appropriate charm, and to rival the accredited seats of cultivated labour in the production of articles of a purely decorative and æsthetic character. If the markets of continental Europe be partly closed against us by the existence of older establishments, or by the force of conventional fashion, or by the obstinate impediments of illiberal legislation, we may still find in the new markets of rising states, in those which have been planted by the adventure of our own race on the plains of America and Australia, a fair field and ample scope for the higher departments of invention and design. The discovery of gold has been the chief instrument in the formation of the markets here alluded to, and it will long continue to be the basis of their prosperity. The importance of that discovery is not to be sought so much in the amount added to the circulating medium, or in a general rise of prices, which is precarious, and in part delusive: it is to be found in the sudden dispersion over vacant countries of men furnished with all the faculties, and feeling all the necessities of civilization, engaged in a description of labour requiring neither capital nor combination, nor considerable consumption of time, but resulting in the delivery of a commodity which, if it does not directly add to the mass of productive capital, is at least always in the highest demand, and subject to the smallest fluctuations of value. In no other inconceivable form could twenty millions' worth of exchangeable produce have been annually raised with such celerity, and no motive save the intoxicating cupidity belonging to the pursuit of the precious metals could have impelled mankind to such immense migrations.

Nor is the consequence of this great movement of the English race—we still follow the thought and repeat the language of Lord Napier—to be measured by the mere value of the precious metals now or hereafter collected, for while one portion of the population set on foot by that primary incentive sift the auriferous soil with increased assiduity, or apply more scientific processes to the reduction of the rock, or carry their insatiable inquisition and predestined power over those desolate empires, escaping from the paralysed grasp of the Spanish colonists, another portion are ever betaking themselves to various kinds of accessory labour, and to the creation of other articles of traffic which, though not in such instant demand, will, in the long run, become a profitable addition to general commerce.

It would not be difficult to show that the wants of other nations and the dissemination of our own are sufficient, if wisely used, to provide abundant employment hereafter for the industrial energies of England. "I also humbly

"think that, whether we regard the government of the country, or the forces spontaneously operating in the ancient and complex frame of our society, there are many causes uniting to afford an intellectual and artistic education to the working orders commensurate to the task which lies before them." First, with respect to the action of government and parliament there is now, perhaps, in principle, as much direct intervention as is consistent with the spirit of our free institutions. In the British Museum, at Hampton Court, in the National Gallery, at the Kensington Museum, and in other repositories of national possessions, the historical examples of arts and manufactures are rapidly accumulating, which we hope to see placed in magnificent and instructive combination, and which will then only obtain their full value for imitative and suggestive purposes. In 78 schools of design, cheap instruction is afforded to 79,000 pupils, whereby the poorer classes have the opportunity of discovering and improving gifts of native genius, and although our public edifices and monuments recently constructed cannot be regarded with unqualified approval, we may at least hope that the Government has a poignant sense of past errors; and it has certainly shown a desire by pecuniary rewards and competitive exhibitions to draw the highest talent to the service of the state. Allied with the Government of England, or sanctioned by our laws, we find many institutions of a corporate character, which though not designed for the encouragement of arts, must yet, in an intelligent and critical age, by their opulence and associations, become powerful vehicles in fostering the principle of good taste.

But it is certain that neither governments, nor corporations, nor societies, can be profitable agents without a generous, responsive, and critical public. History shows how academies may go on teaching and prating amidst general sterility. There will not be intelligent producers without intelligent purchasers. But the industry of England is nourished from a thousand silent and spontaneous sources. "Our treasures are not only laid up in museums, like grain in warehouses; they are also scattered in our homes, like good seed in pleasant and fruitful places. Many do not worship in the public temple who have built domestic altars to the arts. Consult those quiet habitations of the beautiful and good, how many modest deeds and gentle voices attest the prevalence of a beneficent culture."

We offer no apology for re-echoing the noble language of this noble lord. We have our own strong persuasions respecting the swiftness and certainty of our national progress; but although we need no assurances like the above for our comfort, we observe with pleasure that so just an appreciation of the present, and so enlightened an expectation of the future, has already reached the minds of those who have heretofore been slow to learn like lessons.

SOCIETY OF ARTS.

AWARD OF MEDALS AND PRIZES.

The Council of the Society of Arts, on the recommendation of their Committees, have awarded the following Medals:—

To Messrs. Hamilton and Nash, for an "Improved Lock." *The Society's Silver Medal.*

To Messrs. Peter and Charles Garnett, for their "Toothed-Roller Cotton Gin." *The Society's Silver Medal.*

To Mr. F. Jaubert for his invention of "A Method of rendering Engraved Copper Plates capable of producing a greatly increased Number of Impressions," and for his paper explanatory of it, read before the Society. *The Society's Silver Medal.*

To Mr. E. J. Reed, for his paper read before the Society—"On the Modification which the Ships of the Royal Navy have undergone during the Present Century, in respect of Dimensions, Forms, Means of Propulsion, and Powers of Attack and Defence." *The Society's Silver Medal.*

To Monsieur Théophile Silvestre, for his paper read before the Society—"Les Arts, les Artistes, et L'Industrie en Angleterre, depuis la Dernière Moitié du Dix-Huitième Siècle Jusqu'à ce Jour." *The Society's Silver Medal.*

To Dr. J. Forbes Watson, F.R.S., for his paper read before the Society—"On the Growth of Cotton in India, its Present State and Future Prospects, with Special Reference to Supplies to Britain." *The Society's Silver Medal.*

To Mr. Leonard Wray, for his paper read before the Society—"The Culture and Preparation of Cotton in the United States of America, &c." *The Society's Silver Medal.*

To Mr. John Bell, for his paper read before the Society—"Some remarks on the application of Definite Proportions and the Conic Sections to Architecture, illustrated chiefly by the Obelisk, with some History of that feature of Art." *The Society's Silver Medal.*

SWINEY PRIZE.

This year brought with it the third quinquennial anniversary of the death of Dr. Swiney, and the Society, in accordance with the trust imposed on them by the will of that gentleman, have presented the Silver Goblet, of the value of £100, with the gold coin in it to the same amount, to Dr. Alfred Swayne Taylor, F.R.S., as the author of a treatise on Medical Jurisprudence. The goblet is in silver, from a design by Mr. MacLise, and was awarded at a joint meeting of the Members of the Society of Arts and the College of Physicians, held in accordance with the terms of Dr. Swiney's will, on the 20th of January last.

WRITING CASE.

It will be remembered that in the society's report of last year it was stated that the sum of £20, placed in the hands of the council by the Rev. F. Trench and J. MacGregor, Esq., to which the Council added the Society's Medal, as a Prize for a Writing Case suited for the use of soldiers, sailors, emigrants, &c., had not been awarded, none of the articles forwarded having been considered to possess sufficient merit to justify a decision in their favour. The Council then announced their intention to invite further competition. In reply to this announcement twenty-eight cases were sent in, and after a careful examination by the committee they reported in favour of a case manufactured by Messrs. Parkins and Gotto, and the Council have thereupon awarded the prize of £20 and the Society's silver medal to that firm. The retail price of the case is 1s. 6d., including an indelible pencil, but without other contents, which must depend on the selection of the buyer.

FINANCIAL ESSAY.

At the date of the Council's last report, the essay sent in competition for the prize of two hundred guineas, placed in the hands of the Council by Mr. Henry Johnson, to be awarded as a prize for "The best essay on the present financial position of the country as affected by recent events, in which the principle of a sinking fund should be discussed, and also an investigation made as to the best mode of gradually liquidating the National Debt," were under consideration, twenty-two essays having been received. The prize has since been adjudged to Mr. Edward Capps, and the essay has been published. The adjudicators appointed by the Society to report on the merits of these essays were Professor Charles Neate, of Oxford, Professor Waley, of University College, London, and Mr. J. T. Danson, Fellow of the Statistical Society, and their decision in favour of Mr. Capps was unanimous.

MARINE ALGÆ.

The Council in their last report informed the members that no essays had been sent in to com-

pete for the two prizes of £50 and £20, placed in their hands by Sir W. C. Trevelyan, Bart. That gentleman has now increased the amount to £100, and that sum is now at the disposal of the Council as a single prize for "The best Essay on the Applications of the Marine Algae and their products, as food or medicine for man and domestic animals, or for dyeing and other manufacturing purposes. Competitors must give the results of their original investigations on sea-weeds; and they must prepare a series of specimens illustrative of the best modes of collecting, preserving, and preparing the several species. Mere compilations will not be admitted to competition."

The essays, with accompanying specimens, must be delivered at the Society of Arts by the 31st day of December, 1880. Each essay to be marked "Essay on Marine Algae," and to have a motto or distinctive mark attached, which must also be written on a sealed letter containing the name and address of the author.

MONEY-MAKING AT THE ROYAL MINT.

No. V.

To visitors to the Royal Mint, perhaps the last process of the art of coining—the crowning blow to all previous manipulations of the precious metals there, is the most interesting. The weighing machines, with their delicate little forceps, wheels, levers, slides, glass counterpoise weights, and distributing tubes, are unquestionably beautiful, as their action is next to infallible; but they yield the palm, in one respect at least, to the coining-presses. The weighing machines, like Civil Service Commissioners, are capable of reporting upon the merits of candidates for public office, but they do not, like the coining-presses, qualify those candidates for passing current in the best as well as the worst society. Vain would be all past operations indeed without the impressed stamp of the coining-room. The rapid transformation of blanks into finished coins—the covering of their entire surfaces and edges with beautifully engraved devices in the twinkling of an eye, as it were, this it is which astonishes and pleases all who see it.

To describe as accurately as letter-press will allow the manner in which this important change in the complexion, and value, of the assized discs of gold is effected, is now our task, and we return for a moment to the four journey-weights of dried-out pieces. These are advanced to the coining-press-room, and whilst the officer is once more weighing, and the workmen are adjusting the presses for stamping them, we may endeavour to explain the general features of this department, and the mechanical appliances it contains.

The coining-press-room, then, is about 70 feet in length, from 30 to 40 feet in breadth, and, it may be, 15 in height. It contains eight presses, ranged in a straight line, on the vertical screw principle, as constructed in 1810 by Messrs. Boulton and Watt, and these may be said to be at work almost every working day throughout the year. There is in addition a small hand-press, which does only two days' work in the year. The large power presses coin all the current monies for England and the Colonies—except Sydney, which has a small mint of its own—from the florin down through all denominations of silver to the three-halfpenny piece circulating in the West Indies; and from the penny to the quarter-farthing of Ceylon in copper. At the power presses, too, the great majority of the fine silver medals distributed among our noble-hearted and brave sailors and soldiers are struck, though in a different way to the ordinary coinage, as will be hereafter shown. The French toy-press produces only the silver Maunday pennies given by Her Majesty or her agents to poor pensioners on Maunday Thursday, according to ancient custom. As may be supposed, the coining-presses are very heavy castings—weighing very nearly two tons each. By far the greater portion of this metal, however, is thrown into the base of them. They are firmly bolted to foundations of granite of great depth and of immense

solidity, and there is ample reason that this should be so. The beds of the presses, it is obvious, have much to withstand. Millions and millions of heavy blows are continually being struck upon these coiners' anvils, and it is certain that they would yield if not of immense strength in themselves, and well-sustained on their stony seats. At a height of about 2½ feet from the floor, which is of thick, narrow, oaken planking, so closely jointed and tongued as that the smallest coin shall find no crevice through which to disappear—at the height named, a platform covered with diamond-patterned iron plate, and with ample space on all sides of it for truck traffic, surrounds the eight presses. From this platform, at convenient distances for enclosing the presses, spring eighteen oaken columns of a foot square, reaching to the iron girders of an upper floor; and bound together laterally by hollow cross bars of cast-iron, with tension rods passing through them. The cross-bars perform a double office, they unite the columns in pairs, and support regulating buffers which limit the travel of the fly-arms of the presses. Taking now one of the tier of presses as illustrative of the whole, it may be stated that a coarsely pitched, say 5-inch, treble-threaded screw, of about 6 inches diameter, passes vertically through a gun-metal bush or nut in its centre, and leaves a space of say a foot between the lower end of the screw and the planed bed of the press. In this space the die-holders have to be arranged, and in this space all the money is struck.

To the lower part of the screw—and so adjusted as that its flattened end of hardened steel may work freely in a cup or dish, also of hardened steel, belonging to the upper die-holder—this latter is attached. The upper die-holder is supported by rods running quite through the body of the press vertically, and fastened to a collar working on the upper end of the screw. It is guided, too, by steel V pieces sliding over angles of the press, and it is clear, therefore, must rise and fall with any upward and downward movement of the screw. Firmly screwed down to the planed and perfectly level surface of the bed of the press, is the lower die-holder. This is recessed for the admission of the die, and is fitted with three "set" screws for fixing it accurately. The upper die-holder is similarly recessed in an inverted form, but the die once fixed in it is not adjustable. As the press-screw fits its "bush" or nut, and is made to move perpendicularly by adjusting brasses, above and below that bush, so must the upper die-holder and its die move perpendicularly also with it. It is only necessary, therefore, in die setting that the lower die be placed fairly below the upper one, which cannot fail to be rightly placed itself.

To the left side of the press is attached the feeding apparatus, a clever contrivance—now outshone, however, we believe, by a newly arranged "Layer-on," invented for the Calcutta Mint by Mr. Harvey, of that establishment—to which motion is given by means of a flattened vertical rod about three feet in length, working on a fulcrum pin passing through its centre, and the upper end of which slides in the slot of an eccentric quadrant clamping the circumference of the press screw. This feeding apparatus is furnished with a set of brass tubes of the various sizes of the money coined at the British Mint.

Well, then, if an engraved die be placed in the upper die-holder with its face downwards, another die in the lower with its face upwards, with a space say of an inch between the two, and a piece of gold be placed upon the surface of the lower one, it becomes plain that a forcible turn of the screw downwards will inevitably transfer impressions from both dies to the softened metal between them, and, in fact, make it a coin. And this, indeed—of a much ruder character, of course, than any machinery is now made—was the principle of Blondeau's screw-press, of that early period in Mint history when the hammer was superseded, and of which we have before spoken.

Imagining that the explanation so far is manifestly plain, let us take a stand upon the iron platform, and examine a little further into the arrange-

ment by which continuous, rapid, and powerful motion will presently be given to this screw and its appurtenances. The golden blanks are distributed among boys who tenant square holes, fitted with seats, in the platform, and have wire meshed trays beside them for the reception of metal. These boys, however, must await our leisure before putting the blanks through the sovereign ordeal, and the rapid movements of the presses will no doubt atone for our delay.

The screw of which we have spoken, and which is the everything in the Mint coining press—except the life-giving dies—projects above the body of the press, and has fitted and keyed upon its conically-turned end, a pair of fly-arms. These are of about three feet radius, and have on their extremities hollow boxes of iron, which may be weighted according to the nature of the work expected of the press for the time being. These boxes are flat-ended, and fall upon the aforementioned buffers when the press is in action. From the centre of the fly rises a gracefully-formed trumpet-shaped hollow shaft, through the medium of which motion is transmitted to the press. The mouth of this trumpet is on the first floor, and we will therefore adjourn to that place. So! here are levers, rods, counterpoise weights, pumps, &c., and we are evidently behind the scenes. But let us look first to the mouth of the trumpet. This is about three inches above the floor, through which the trumpet shaft has passed, and between the iron girders of which brass bearings guide and steady it. A rod suspended to a vibrating beam overhead, runs down through the trumpet shaft, and is connected with the screw of the press. The other end of the vibrating beam has a rod depending from it, and which at its lower end on the same floor is attached to the piston of a vacuum-pump. The cylinder of this pump is in communication with a great vacuum-chamber—of which we must presently speak again—by means of a small pipe, and when exhausted the atmosphere presses on its piston with just sufficient force to make it balance through the beam the weight of the screw-pin of the press, its fly-arms, and upper die-holder. So perfect is this state of equilibrium maintained, that if we take up the trap in the floor, and ask the even youngest boy to move by its fly-arms the press he is attending, we shall find that he can do it with the most perfect ease. The fly-arms are made to stand still indeed by these means at any point of the stroke of the press desired. This is a great convenience in setting the dies. The press may be moved up or down with the completest readiness, and thus hand-tests may be made of the work, and impressions of the dies taken before the power is applied.

A notched rectangular lever of wrought iron, of considerable strength, and say twenty inches in length, is keyed upon the projecting upper end of the trumpet shaft, and lies close to the surface of the floor. The lever has a sliding steel box fitted upon it, and this is furnished with a key by which to fix it at any distance from the centre of the press as less or more power is required to be transmitted, or as, in fact, small or large monies are in the process of manufacture. Through this box, too, a shifting steel pin passes, and this allows a connection to be made with a horizontal rod of wrought-iron working over a guide immediately above the floor, and attached to a "horse-head" crank with a rod and vacuum-pump and great vacuum-chamber beneath it. Here, then, it will be seen that the communication is made perfect with the reservoir of power—as the vacuum-chamber is, although, as the "used-up" traveller said of the dome of St. Peter's, "there is literally nothing in it." We will now descend therefore once more, and after examining the arrangements of the vacuum department, will induce the boy so patiently awaiting in his hole our coming, to put a press in motion.

The vacuum-chamber is a cylinder of cast-iron about sixty feet long and two feet in diameter, and is placed horizontally parallel to the tier of coining presses, from which a wall separates it. From this reservoir—if we may so name it—arise

at intervals corresponding with the distances of the presses from each other and with their number—that is, eight—a series of three-inch pipes, fitted with indexed stop-cocks intermediately to the vertical vacuum-pumps to which their upper flanged ends are bolted. The press-pumps are fitted with one disc valve opening into the vacuum-chamber and another to the great atmospheric ocean itself. There are communicating lines passing through tubes—and which lines hungry Mint-mice have been known to gnaw through during the night—to the press-holes, and these lines give the attendant sprites who convert buttons into sovereigns control over the inner and the outer valves. We now see that all is ready and we will return to the coining press-room. The patient and industrious boy we see has amused himself whilst waiting for us by repolishing all the brightwork about the machine until it shines like the bars of a palace grate—good boy!

He has also charged the tube of his feeding apparatus with some of our old friends, the blank pieces of gold. The tube has two grooves down its sides, and these enable him to drop *rouleaus* of blanks *flatly* into it with ease. Now observe, the dies are in their places, one above and one below, and like two seals—not those of the Arctic Seas, but letter seals—are ready to impress on both sides any softer material that may be made to interpose between them at the moment that power is applied to bring them together. The attendant now stands for a moment on the platform and puts the press up, where perforce of upstairs pump it remains; he next causes the feeder to clasp one piece from the bottom of the tube—and more than one at a time cannot find room to pass out—and to carry it forward to the lower die. It is placed so exactly as to cover the Queen's "image and superscription" completely. The vertical rod, worked by quadrant aforementioned, is now attached to the feeder in so simple a manner as to disengage itself readily if by any chance a distorted blank objects to leave its tube or be stamped upon, and one of the starting lines is pulled by some little force—the resistance of a small spring having to be overcome—and fastened to a stud beside the boy in the press-hole. Nothing moves as yet, and the fastening of the line has merely allowed a tappet to close the outer valve of the press-pump. Now behold! the Genii of the press-room touches another cord—not chord—and the effect is miraculous; he has opened the inner valve, and hey, presto! the air below the piston has vanished and the atmospheric column has carried it *instantly* to the bottom of the cylinder. The press-screw has followed by dint of rods and levers; and as an interiorly milled steel collar which nicely fitted over the neck of the lower die and rested on a tripod spring arose by force of that spring and encircled the piece of gold at the moment that the upper or reverse die struck it, it is clear that both the head and the tail, and also the serrated edge or milling were given to the blank at that one blow. The milled collar acted a double part indeed, it prevented the undue and irregular expansion of the gold as occurred in the old sledge-hammer coinage, and it formed a mould from which the edge of the sovereign became by sheer pressure within it serrated. Whilst the first of our batch of sovereigns was getting its impressions, the feeder slide came back self-actingly and singled out another piece; this it now carries rapidly forward to the die, and as the milled steel collar has been made—also self-actingly—to sink again below the surface of the die, the coined piece resting on it is unceremoniously pushed away by the new comer and thrown down an inclined copper slide in a finished state, to a tray placed to catch it and its lovely companions. The feeder now makes its deposits of piece after piece with wondrous precision, the collar alternately rising and falling, the boy keeping up the supply of food to the hungry "critter" who disposes of his golden rations at the rate of from sixty to seventy pieces per minute, and bright, beautiful, glistening, tempting, mischief-making,

useful sovereigns are thrown off with marvellous speed. The levers, springs, weights, counterpoises, valves, and other portions of the vacuum arrangements go on with their task so long as the press attendant keeps the line on the stud beside him; but, wishing to stop all, he has nothing to do but release it, and his money-making forthwith ceases.

When an accumulation of coins of some magnitude occurs in the tray, and this is soon, they are taken up by workers in attendance, and carefully examined to see that they are free from spot or blemish, and fit to pass forth into the "wide wide world" on their mingled missions of good and evil.

THE SEWING MACHINE:

A SKETCH OF THE HISTORY OF ITS USE.

No. II.

THE sewing machine is used either to ornament fabrics or to unite them.

During the first half of the present century several machines, designed chiefly for ornamenting fabrics, were invented in England and France; and a considerable number must have been introduced among the embroiderers, lace-makers, glove-makers, and stay-makers of both countries. Between the years 1844 and 1850 a few machines for uniting fabrics by means of a running or basting stitch were used by bleachers, dyers, umbrella-makers, and others, for the purpose of tacking materials together. The number of machines of all kinds, however, at work in Europe in 1850 must have been so few that the name of a sewing machine could scarcely have been known even in manufacturing towns like Nottingham in England, or Lyons in France.

In the United States, sewing machines were first introduced into public notice and general use. The Americans needed machinery for uniting fabrics rather than for ornamenting them. So great was the need of machines for plain sewing that improvements were made at different places almost simultaneously; and even now, after years of litigation, it is impossible to decide with certainty who was the first inventor in America of any considerable improvement in the sewing machines. During the years 1850, 1851, and 1852, the three largest manufacturing establishments in the United States commenced business, and for several years they almost monopolized the trade. The high price of hand-sewing had prepared the people to welcome their machines; while their competition and extensive advertising soon overcame the hostility of the working classes. Sewing by machinery became, in a short time, a more important branch of national industry than either spinning or weaving by machinery. Manufacturers of boots, saddlery, and clothing of every description were the first to patronise the new invention. At present there are many large establishments in which between 100 and 200 machines are used in shirt-making, quilting, dress-making, &c. In the Southern States machines are used extensively to make negro-clothing. Within the past two or three years families have commenced to purchase them for domestic use, and already the sewing machine has become almost a necessary article of household furniture. Steps have been taken in many places toward their introduction into the female departments of the public schools, as a part of the regular course of study, and it is considered far more desirable that young ladies should understand the proper manipulation of a sewing machine than that they should become good pianists or indifferent artists. In some neighbourhoods one family will purchase a machine and hire out the use of it to persons not rich enough to own one, or several families will unite in the purchase of a machine, and pass it around as needed. Many seamstresses who, at first, borrowed money to buy one, now own two or three, having other seamstresses to work those for which their own hands do not suffice. Full one-half of the machines now made are sold to the laborious class of persons known as needlewomen, sewing girls, and em-

ployées in manufacturing concerns. It is not extravagant to say that three-fourths of all the sewing done in the city of New York is executed on machines—so profitable and so popular has this work become.

As a consequence of this rapid introduction and extensive use of sewing machines, a great improvement has taken place in the quality of machine needles, sewing silk, twist, thread, &c. The Americans now boast that they can produce thread far superior to any of foreign manufacture in strength and evenness of texture.

Since 1850 the sewing machine trade in Great Britain has merely followed, though at a great distance behind, the course of trade in America. Probably one-fifth of all the sewing machines used in this country have been imported from the United States. Almost all the machines in use are owned by manufacturers of shirts, boots, stays, caps, saddlery, and ready-made clothing. Its use is confined to places of large trade, such as London, Manchester, Nottingham, Glasgow, the north of Ireland, Dublin, and Limerick. The prices of machines have been so very high that few, or almost none, are owned by the working classes; and probably this is the principal reason why the workmen resist their employment. A "family sewing machine" is almost unknown in Great Britain.

Since our last issue, we have been informed that one of the first patentees of the sewing machine in Great Britain has withdrawn the suit which he had commenced against some manufacturers of ready-made clothing who were using the machines of another patentee. We are pleased to find he has pursued, in this case, the wiser policy of paying the expenses already incurred in his prosecution, rather than meet a final defeat in attempting to control the sewing machine trade of England. We may now hope that the people of England will be permitted, without molestation, to select from the best machines that can be brought into the market. Patentees should endeavour to settle their disputes among themselves without quarrelling with their customers.

High Speed Steam Navigation and Steam-ship Perfection.—Can perfection be defined in the form of a Steam-ship, a Propeller, or any other mechanical appliance? A proposition for the solution of the Scientific World, and for the consideration of the British Admiralty. By ROBERT ARMSTRONG. London: E. F. Spon, 19 Bucklersbury, E.C. 1859

THIS production, with its very attractive and particularly mysterious title, reminds us forcibly of a narrative which must be familiar to the most incipient entomologist, beginning—"Will you walk into my parlour, said the spider to the fly? 'tis the prettiest little parlour that ever you did spy: the way into my parlour is up a winding stair, and I have many curious things to show when you are there;"—for we know of old that Mr. Armstrong is very liberal in his invitations to the "scientific world," the "British Admiralty," and other acquaintances of his to walk into his parlour ("parley"); that the way into it is an extremely round-about one; that the things he has in it are exceedingly curious; and finally, that when he once gets you into his mazes and meshes it is a most difficult thing to extricate yourself from him. Indeed, the faculty which Mr. Armstrong has for spreading words and figures in complicated forms is so wonderful that, were his knowledge of geometry and his love of symmetry equal to the spider's, he would almost stand upon a level with that clever creature in the art of spinning webs. We must do him the justice, however, to say that he is void of that cruel and selfish disposition which his little rival so wantonly manifests.

There is, to speak more gravely, a very true sense in which the man who writes and publishes a book invites the reader into his parlour—his "parlour" being that mental region or apartment in which he dwells. The knowledge which

a man possesses constitutes the furniture and decorations of that apartment, and it is by means of it that he proposes to entertain the reader. If, therefore, on entering the apartment we see at a glance that the whole aspect of the place is uninviting or repugnant to us, it is only wise of us to retreat forthwith. And this, we must say, is the purpose we have formed in reference to Mr. Armstrong. We do not like his "parlour" at all; his furniture is all rickety and unsound, and his decorations coarse and extravagant. We do not find in his writings any clear understanding of existing science; any sufficient appreciation of the present condition of our knowledge; any orderly statement of what he presumes to be erroneous; or any systematic endeavour to explain his own theories. Nor, indeed, do we even find any indication of the mental power and culture which are indispensable in a man who presumes to handle such a subject as that on which Mr. Armstrong here addresses us.

We write this without a shadow of ill-will to Mr. Armstrong, and with the hope that he will not persist in estranging all sound scientific men from him. That he is now running the risk of this is most evident. Months ago Mr. G. P. Bidder openly repelled him at the Institution of Civil Engineers, saying that he (Mr. Armstrong) was either so insensible or so indifferent to the arguments of the cultivated members of that Institution, that further argument with him "would be as useless as to attempt to hold a conversation with him in a language he did not understand;" and Mr. Armstrong himself innocently tells us that "an eminent engineer has used precisely the same words." We not only adopt them, but go further, and say that scientific men who converse with Mr. Armstrong do actually employ a language which he does not understand. And the reverse is equally true—scientific men do not understand his language. He makes a very free use—too free a use—of certain great names, but we believe he fails altogether to comprehend what the persons whom he quotes mean in much that they say. Our opinion is, that he is wholly mistaken in supposing that he is in any way competent to deal with the subjects on which his mind appears to have fastened. We do not for a moment doubt the excellence of his intentions, be it observed; it is of his inability to give effect to them that we speak, and of that alone.

The Polymeter, or Quintant. The Practice of a New Sector, as used in Trigonometry, Surveying, Fortification, Gunnery, Engineering, and Astronomical Observations. By FREDERICK R. A. GROVER, M.A., Chaplain to Her Britannic Majesty's Consulate at Cologne. Cambridge: Deighton, Bell, and Co. London: Bell and Daldy. 1859.

THE author of this little work is the inventor of an instrument called the Polymeter, which is represented as answering all the purposes of—1, a sextant; 2, a double sextant; 3, a surveying magnetic compass; 4, a level; 5, an artificial horizon; 6, a dial; 7, a set of scales; 8, a protractor; 9, a thermometer; 10, a gunner's quadrant; and 11, a pair of callipers—the whole being brought into the size and shape of a thin memorandum book, which its cover forms. In addition to all this, it likewise is a "trigonometer"—a new instrument for measuring heights and distances, doing trigonometry without logarithms, &c. The pamphlet before us is a handbook for the use of those who are fortunate enough to possess this invaluable instrument, and must, of course, be purchased by all such persons. To those who do not know the instrument the pamphlet will make its nature and value known.

Chart of the Royal Navy of Great Britain from the Earliest Period of History, Compiled from Historical Publications, Old Records, Parliamentary Returns, and other Authorities. London: J. D. Potter, 31 Poultry, and 11 King-street, Tower-hill. 1859.

THIS chart, which has been compiled, we believe, by Mr. Frederick Perigal, exhibits at a glance the rise and progress of the Royal Navy,

showing its total force in each reign, and the numbers of ships in the several rates since the system of classification was adopted by Charles I. The relative strength of the navy at the principal periods of our history may, therefore, be readily compared by means of it. The sheet has been very carefully printed by Messrs. Eyre and Spottiswoode, and is issued either unmounted, or mounted and bound strongly in cloth. We cannot vouch for the accuracy of the compiler, as he has not thought fit to verify his figures by distinct references to the sources from which he has drawn them, and we know how easily mistakes may be made in such matters. We see no reason, however, to question Mr. Perigal's care in this respect, and we know that he has for some years made the navy a subject of study. For general purposes such a compilation as the present will be very useful.

VAN HECKE'S SYSTEM OF VENTILATION.

MUCH attention having lately been drawn to the system of ventilation lately introduced by Van Hecke in many continental hospitals—apparently with great advantage—we have been anxious to lay some correct description of the system before our readers. This, an article in last week's number of our excellent contemporary, the *Builder*, opportunely enables us to do.

"Of the application of Van Hecke's plan to one of the pavilions of the Hospital Beaujon, and a highly favourable report by a Government commission on the subject, we had some time since heard, and were favoured," says our contemporary, "by Mr. J. Bonomi, with a special translation of an elaborate paper by the reporter on that commission, Dr. Grassi, who had instituted an experimental investigation of the system for his own satisfaction, after the commission of which he was the reporter had favourably reported on it to the French Government. Of this translation we propose now making some use; the more especially as we find that Van Hecke's mode of ventilation continues to be preferred to all others in new French hospitals, to which it has since been applied."*

Dr. Grassi, in the outset of his dissertation, after some allusion to the mode of ventilation and warming long in use at the Hospitals Neckar and Beaujon, and to the commission appointed to examine the new system of Dr. Van Hecke which has been tried in the Pavilion No. 4 of the Hospital Beaujon, thus proceeds to describe that system:—

"The warming of the Pavilion No. 4 of the Hospital Beaujon is performed by means of a calorifère-stove situated in the cellar-floor. Air is conveyed to this stove by a cylindrical channel of zinc, 75 centimètres (2 ft. 5½ in.) in diameter, which, after running horizontally through the vault, is received into a vertical shaft of masonry opening out in the garden at about 2 mètres (about 6 ft. 7 in.) above its surface; from this source the air is derived. After the air has passed through the tubes of the calorifère and become warmed, it enters a large pipe, to be distributed by it in the three wards (one above another): before, however, reaching them, it passes over a pan of water to supply it with a suitable quantity of moisture. By this arrangement the air transmitted to the wards is derived exclusively from the garden, and not allowed to mix with the air of the vault. Instead of permitting the air to circulate in the calorifère, it may be sent to the wards in a direct course, which bears the same relation to the channel of the calorifère that the chord does to its arc. At the commencement of the calorifère tube there is a moveable register for the purpose of giving such a direction to the air as may be required, either for warming it, or allowing its use

at its natural temperature. The register, when partly opened, may even permit a mixture of the two at different degrees of temperature, and moderate the warmth of a ward for the moment become overheated. The air conduit (or pipe) enters the ground-floor ward in its centre at the floor level, through the middle of a cast-iron drum of four vertical sides, furnished with perforated doors for admitting the air into the ward. The tambour or drum incloses some wire shelves, on which linen may be placed, and drinks for the patients to be warmed. The air-pipe debouches on the floor-level through an opening of 75 centimètres (2 feet 5½ in.) diameter, in which is inserted a vertical tube of 60 centimètres (1 ft. 11½ in.) diameter, rising to the first floor; between these two tubes there exists an annular space, permitting a portion of the air to be arrested on the ground-floor. Thus the air introduced is divided into two portions; one admitted to the ground-floor, the others continuing upwards for the use of the upper floors. A register, regulated by a quadrant, permits the reduction of the section of the tube, and of varying the volume of air for each of the floors. If the register is entirely closed, the whole of the air would be arrested on the ground-floor: by opening it, more or less, the air for the two upper floors is increased at pleasure. On the first floor there is an arrangement like that on the ground-floor, a register for stopping a certain volume of air, and for allowing the rest to rise to the second floor, where the second column terminates, and a tambour only exists, in every respect resembling those of the lower floors. Thus fresh air, serving both for warming and ventilating, is admitted into the centre of the wards, entering through wide openings, so as not to acquire a great velocity, and produce disagreeable currents. The air which has been harboured (*ajouré*) in the wards escapes from them through four evacuating channels in their corners or angles—a number too limited, in my opinion; but the pavilion being already built where the system of ventilation was adapted to it, a greater number would have occasioned a considerable outlay for cutting chases in the walls, or for placing the channels on the wall surfaces with a very disagreeable appearance. The three channels at each angle,* and which correspond with the three wards, rise side by side vertically to reach the loft, where they are received into a horizontal zinc pipe, one at each of the four corners, which unite in the centre of the loft in a tambour, capped with an evacuating cylinder of zinc, 75 centimètres (2 ft. 5½ in.) in diameter. At the intersections of the air-escape channels from the wards with the receiving channels of the loft, registers are fixed, by which the openings may be regulated, and, consequently, the draft or extraction from each of the wards. The air from the wards has, besides the evacuating channels above-named, an exit for escape through the water-closets by an opening in the ceiling, which also communicates with the channel in the loft. The air from the ward, entering into the water-closets through an opening in the lower part of the door, rises towards the evacuating opening in the water-closet ceiling, sweeping through and carrying away in its course all smell. The ventilation is not effected through the water-closet basins, as at La Ribosière, the seats being closed, and the ventilation acting exclusively upon the atmosphere within the water-closet; it is quite sufficient, and in no hospital have I found the water-closets so completely rid of smell as in the Hospital Beaujon.

"By way of concluding what refers to the introduction and exit of air, I must mention a source of pure air considered as accessory, which, however, is not unimportant:—On the ground-floor at the entrance to the cellaring is placed a small steam-engine, of which I shall presently speak. The smoke-flue from its furnace, united to that from the calorifère-stove, is surrounded by a concentric enclosure, the lower end of which is

* It seems needful to add here, "of the upper ward." TRANS.

* A pamphlet entitled "Remarks on Ventilation, with Extracts from Official Reports, on the Combination of Ventilation and Warming;—System Van Hecke. By Wilson Weatherby Phipson, C.E." (Printed by H. M. Pollett, 35 Aldermanbury), has recently been forwarded to us, which contains many allusions to the favourable results obtained by means of Dr. Van Hecke's system, but no particular description of the plan itself.

open to the outer pure air, and draws it in through its orifice in the garden. This air circulates in the annular space round the smoke-pipe, in contact with which it becomes warm as it rises to the top of the building. This air-flue is situated in the thickness of the wall separating the staircase from the wards; at the level of each story it presents three openings, one into the ward, one towards the stairs, and the third into the two-bedded room. These openings afford a passage for the warm air during winter: in the summer season it is allowed to rise to the upper part of the building, where it disperses itself; but Mr. Van Hecke was desirous to turn this warm air to account, by causing it to enter the loft used as a drying-chamber. When the upper orifice of this air-flue is closed, as is the case in winter, the warm air diffuses itself in the wards, and in the staircase, of which it keeps up the warmth. In summer, when the upper orifice is entirely open, the smoke-flue draws upon the air within the wards, and thus produces an increase of ventilation.

"Such is the channel-system for the passage of the air derived from the garden, and finally escaping through the common flue. Now let us consider the moving power. I have before mentioned the small steam-engine at the entrance to the cellaring; it is intended to keep in motion a ventilator, which, in the first instance, Mr. Van Hecke had placed in the upper part of the tubing within the flue or chimney of the loft. A band or strap transmits the movement from the ground-floor to the loft; the ventilator then produces a suction-draft from the air of the wards. The apparatus of Mr. Van Hecke produced ventilation by (appel) suction by mechanical agency. Since it was fixed an important addition has been made to it. Mr. Van Hecke has placed a second ventilator, identical with the first, in the lower indrught channel, where the column of air takes its rise within the vault. On connecting this ventilator with the machine, it drives into the wards the air which it inspires from without, and thus produces a ventilation by injection analogous to that produced by the apparatus of Messrs. Thomas and Laurens, at the Hospital La Ribouisière. In this manner the apparatus is arranged to allow of ventilation by suction, on putting the upper ventilator in motion, or by injection when the engine is in connection with the ventilator situated in the lower part of the building; the change being effected simply by the band which transmits the motion, an operation requiring but a few minutes. The ventilator of Mr. Van Hecke is composed of two (*palettes*) fans or blades, fixed to two stems, which are inserted perpendicularly on the axis of rotation, and inclined from fifty to sixty degrees. A peculiarity distinguishing this ventilator is, that the inclination of the fans is not constant, but varying with the speed of the rotary movement. The boiler of the engine warms the office on the ground-floor, in which are arranged pans for poultices, and a warm-linen closet. A portion of the steam, after giving motion to the engine, is sent to the upper floors, where it heats the water required by the patients; but the greater portion, which might be usefully employed, is for the present wasted."

Dr. Grassi then proceeds to show how the effects of the system are indicated by anemometer, connected with a contrivance of M. Van Hecke's. He then adds:—

"In order to complete the description of this system of warming and ventilating, I have to notice an apparatus not yet fixed, but which is now being constructed by M. Van Hecke, and to be placed within the stone-built channel, which from the cellar leads into the garden for air. This apparatus is intended to cool the air in summer, on its way to the wards. It consists of two cylinders placed horizontally one above the other, at 1 m. 50 s. (4 ft. 11½ in.) apart. On the axis of the upper cylinder is a pulley to receive the movement of the axletree. The under cylinder is plunged into a trough of water, which may be obtained of the temperature of well-water, or be cooled artificially by pieces of ice, should it be requisite.

GIBSON'S PATENT STEERING APPARATUS.

Endless bands pass from one to the other of these cylinders, which revolve simultaneously. The air circulating in the channel is forced to pass over these constantly moist bands, and thus acquires a much lower temperature."

The use of steam-power, we may add (says the *Builder*), is only requisite to Van Hecke's system on a large scale. In ships and elsewhere, where manual labour can be easily or economically applied, or is sufficient for the purpose in view, no steam-power is necessary to ventilation on this plan; and in dwelling-houses the ventilator has even been put in action by clockwork and weights. A French admiralty report speaks favourably of the system as applied on shipboard, where one man works it at a time. French Government reports speak strongly in its favour, as adopted at the Hospital Necker, for ventilation, heating, and cooling. The Hospital L'Asile Impériale de Vesinet, near Paris, has had Van Hecke's apparatus applied to it, and it has been brought into use in other hospitals and public buildings in France and elsewhere, and is ordered for hospitals now in course of erection at Chartres, Lyons, &c.

GIBSON'S PATENT STEERING APPARATUS.

MR. W. GIBSON, of St. Leonard's-road, Middlesex, has just obtained patents in England, France, &c., for a steering apparatus of novel and promising construction. His invention consists in working the rudders of ships and other vessels by means of an endless screw shaft, which gives motion to a nut connected to a lever centred on a fixed stand-end at one end, and connected at the other end to an arm projecting from the rudder head, through a connecting rod. The steering wheel is keyed on or otherwise fixed to the endless screw shaft, and on turning the wheel in one direction or the other the required motion is communicated through the nut, lever, connecting rod, and arm to the rudder. The lever is slotted to allow of the connections and the nut and the rudder arm moving therein.

Fig. 1 of the accompanying engravings is a view of this apparatus taken from the side of a ship or vessel; Fig. 2 is a front view of the same. *A* is the deck upon which are firmly fixed by bolts or otherwise two standards *B B*, carrying bearings, supporting a screw *C*; *D* is the rudder-head or post, and *E* an arm or lever projecting from side thereof; *F* is a vertical rod carried up from the arm *E*; on the upper end of this rod a small roller is placed, which rides in a slot in one end of the lever or bar *G*. The opposite end of this bar or lever is centred in a pin or stud supported on a standard *I*. The lever *G* is also slotted, and in the slot a pin rising from and connected to a nut *H* works; a friction roller is placed on the pin, where it moves within this slot. The screw *C* passes through the nut. On the tiller-wheel *K*, which is keyed on one end of the screw *C*, being

turned, the nut is moved to or fro, moving with it the lever *G*, which through the rod *F* and arm *E* turns the rudder.

SHAND AND MASON'S NEW STEAM FIRE-ENGINE.

SOME interesting experiments were made on Friday last at the Waterloo-bridge-wharf, with a view of testing the efficiency of a new steam fire-engine which has just been completed by Messrs. Shand and Mason. This engine is the second of the kind that has been made, but in the construction of the present such a considerable reduction of weight has been effected as to materially extend its sphere of usefulness, while it is anticipated that others of still lighter proportions may be built. The whole machine is mounted on high wheels, with a fore-locking carriage; and is, of course, intended for rapid transit by means of horses. The box contains the hose and implements, with a driving seat and space for firemen. Its extreme dimensions are 12½ feet long by 6 feet 5 inches wide, and 8 feet high without chimney. The total weight, including firemen and all implements, is nearly three tons, or almost double the weight of the ordinary Brigade engine. This increase of weight is apparently the only disadvantage which it possesses when compared with the common Brigade engine; in all the other and more important qualities the superiority of the steam fire-engine is so great as to leave no room for comparison with any other. Like the common fire-engine, this one by steam can be worked either with a suction pipe, or water may be drawn from the cistern, which forms part of the engine itself. The steam cylinder and pumps are made entirely of gun-metal; the valves of india-rubber, as in the floating steam fire-engine; and the whole machinery is of the simplest and strongest construction, and not liable to be damaged by any amount of jolting over rough roads. The boiler is of the upright tubular construction, affording ample means for superheating the steam; there are 199 brass tubes, 1½ inch outside diameter, and 15 inches long. The fire-box is of copper, 3 feet 4 inches diameter; the cylinder is 8½ inches diameter, with 6-inch stroke; one water cylinder is 6 inches diameter with 6 inches stroke, the other 7½ inches diameter with a 4-inch stroke, the two being equal in cubic contents. In designing this engine other important circumstances besides obtaining the best theoretical steam pump have had to be taken into consideration, such as weight, bulk, means of transit, and accommodation for hose, implements, &c. The London Brigade engines have pumps consisting of two single-acting cylinders, 7 inches diameter and 8-inch stroke. The average rate of working at fires is not more than 40 strokes per minute, and, as the cylinders contain 616 cubic inches, it follows that a London brigade engine delivers, at its average rate of

SAMUEL AND NICHOLSON'S PATENT PADDLE-WHEEL CONDENSERS FOR MARINE ENGINES.

working, 88 gallons per minute, being worked by 28 men. The water cylinders of the steam fire-engine contain 340 cubic inches, and, as it can be readily worked at no less than 218 strokes per minute, it will thus be equal to three Brigade engines at their ordinary rate of working. The rapidity with which steam can be generated is, of course, an important point in the construction of a machine required for duty on the most sudden emergencies, and this point had been well and satisfactorily ascertained before the trials of Friday last. Nevertheless, in the course of the experiments it was demonstrated that a pressure of 10 lb. steam could be generated in six minutes from the moment of lighting the fire; a high pressure was obtained in 10½ minutes, and the engine was immediately in full work. Of course, in the case of an engine of such description being generally adopted, the fires would always be kept laid, and lighted while the horses were being harnessed; so that the whole machine would be in full motion on its way to a fire. Before the trial the boiler was overcharged with water, part of which was run out before the fire was lighted and found to be cold by the spectators. The jets used were ½, ¾, and inch, in succession, the changes being accomplished by means of a stop-valve on each of the two lines of hose without stopping the engine. This feature will be of great use at a fire. A mast was placed on the bridge, the height from high water to top of mast being 82 feet; the height attained by the ½ jet was considered to be 14½ feet, and the horizontal measured distance 16½ feet; the inch jet went 120 feet perpendicular and 50 feet horizontal. Gentlemen from the various insurance companies, and others interested in fire-engines, were present.

At 6 P.M., on the 6th inst., a second trial took place at the South Kensington Museum, in the presence of Mr. Dilke, Mr. Cole, Captain Fowke, Mr. Braidwood, and other scientific gentlemen. The engine was started under a pressure of 25 lb. in 9 minutes from lighting the fire. The only indicator of height was a tree 70 feet high. The ½ jet was considered to be 150 feet in height, and the inch 130; the measured horizontal distance was 168 feet with the inch jet. It was considered by those who were present at both trials that the engine worked better at the second trial than at the first.

PLYMOUTH AND LIVERPOOL TELEGRAPH.—The submarine cables connecting Holyhead with Liverpool have been successfully laid by Messrs. Glas Elliott, and Co., for the trustees of the Mersey docks. The old semaphore system, which has been in use up to the present time, will be immediately superseded by electric communication between these important points.

SAMUEL AND NICHOLSON'S PATENT PADDLE-WHEEL CONDENSERS FOR MARINE ENGINES.

MR. SAMUEL, C.E., of Great George-street, Westminster, and Mr. Nicholson, engineer, of Bromley, have together obtained a patent for a very novel kind of condenser for marine steam-engines. Their improvements relate to such engines as are employed to drive or to work in the neighbourhood of paddle-wheels, water-wheels, or other apparatus by which the agitation and dispersion of cold water are produced in their ordinary working. We will describe and illustrate the improvements more particularly with reference to their application to paddle-wheel steam vessels.

The invention consists primarily in the employment of surface condensers of any approved form within the paddle-boxes, or otherwise by the side of or behind the paddle-wheel, in order that the water which the wheel, while in motion, is continually throwing up may be received upon or come in contact with the exterior of the condensers and effect the condensation of the steam within them. The invention further consists in employing a supplementary or donkey-engine for pumping the feed water into the boiler or boilers, and a supplementary boiler, or boiler compartment, for generating from the salt water of the sea sufficient steam to supply, when condensed, the waste of water which occurs by leakage in the main engine and by other causes of loss. The feed pumps of both the salt and the fresh-water boilers may be worked by the donkey-engine, which is itself ordinarily driven by steam from the salt-water boiler by preference. Air pumps may thus be dispensed with, as the condensed steam from the surface-condensers falls by its own gravity to the feed pumps. It is evident that where a screw-propeller and paddle-wheels are used in the same vessel, the condensation of the whole of the steam used for giving motion to all of them may be effected by means of this improved arrangement of condensers in connection with paddle-wheels.

Fig. 1 is a transverse section of so much of a paddle-wheel steamer as is necessary for the explanation of the manner in which they prefer to carry the invention into effect; Fig. 2 is a longitudinal section, showing the condenser and arrangement of boilers and donkey-engine; *A A* are ordinary boilers; *B* is a supplementary salt-water boiler; *C* is the condenser formed of side-plates *a a* and top and bottom plates *b b*; *c c* are a series of tubes open at both ends, and fitted steam-tight between the plates *a a*; *D* is a donkey-engine; *E* the exhaust pipe leading from the cylinder into the condenser; *F* is the steam pipe leading from the salt-water boiler *B* into the donkey-engine; and *G* exhaust pipe conveying the steam from the

donkey-engine into the condenser; *H* is a pipe for supplying the fresh water from the bottom of the condenser to the feed pump; *I* from whence it is pumped through the pipe *K* into the fresh-water boiler; *L* is the pump for supplying salt water introduced through the salt-water supply pipe *M* to the boiler *B* through the pipe *N*; *O* is a cold-water pipe for the condenser to be used at starting until the paddle-wheel has commenced to throw the cool water up to the condenser.

ROYAL AGRICULTURAL SOCIETY'S SHOW.

THE Royal Agricultural Society has issued the following programme of their proceedings at the ensuing Warwick meeting:—

TUESDAY, July 12, and WEDNESDAY, July 13.—The implement yard open from ten o'clock in the morning till six o'clock in the evening, on Tuesday; and from seven o'clock in the morning till six o'clock in the evening, on Wednesday; at an admission-charge of 2s. 6d. for each person. Machinery will be shown by the exhibitors at work on each of these days.

The judges to inspect the live stock, and to award the prizes.

Public trials of the steam cultivators on land in the neighbourhood of the city during such hours as the stewards may determine.

At one o'clock (or as soon after as all the judges shall have delivered in their awards, of which notice will be given) the public will be admitted into the cattle-yard on the payment of 6s. each person, at the special entrances; members of council and governors of the society being admitted by tickets to be purchased at the finance department of the society at the show-yard; and exhibitors of live-stock on producing their exhibitor's ticket. Arrangements have been made for distinguishing the animals that have won the prizes immediately the judges have made their awards. At eight o'clock in the evening the cattle yard will be closed.

THURSDAY, 14.—The general show-yard of cattle, horses, sheep, pigs, and implements open to the public from six o'clock in the morning till six in the evening; admission 2s. 6d. each person.

FRIDAY, 15.—The general show-yard open to the public from six o'clock in the morning till six in the evening; admission 1s. each person.

General meeting of the members in the Shire Hall at ten o'clock in the forenoon.

PRESIDENT.—His Grace the Duke of Marlborough.

STEWARDS OF DEPARTMENTS.

Cattle.—Mr. Robert Smith, Mr. Milward, Mr. W. Fisher Hobbs.

Implements.—Mr. Barnett, Mr. H. B. Caldwell, Mr. E. Pope, (Lord Leigh, Steward-Elect).

Cheese and Wool.—Mr. Thomas Pain.
Finance.—Mr. Raymond Barker, and Mr. Wilson (of Stowlangtoft).
Show-Yard Refreshment.—Mr. Humberston, M.P.
Show-Yard Receipts.—Lord Portman, Mr. Wren Hoskyns, Mr. Torr, and Mr. Wilson (of Stowlangtoft); Mr. Milward, Mr. W. Fisher Hobbs.
General Arrangement of Show.—Mr. Brandreth Gibbs.
 By order of the Council,

•R. T. BRANDRETH GIBBS,
 Hon. Acting Secretary, *pro tem.*

By the regulations of the society all persons admitted into the show-yard, or other places in the temporary occupation of the Society during the meeting, shall be subject to the rules, orders, and regulations of the Council.

BOAT-LOWERING APPARATUS.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—Permit me to offer a few remarks on a letter of Mr. Charles Clifford which appears in your last number. Whether or no I be held competent to form a correct opinion on the subject, I would leave, with all due deference to the inventor himself, to the decision of those officers whose vessels have been fitted with his "lowering apparatus" for some length of time, rather than to those who have merely witnessed its working during the ordinary trials.

In the first place, with regard to the impracticability of adjusting the length of pendants to meet every contingency, I am ready to admit that the light-draught and the load-draught in a man-of-war vary but in a trifling degree with the ordinary consumption of coal; on the other hand, in large mercantile steamers such as those of the Peninsular and Oriental and Royal Mail Companies, which are constantly under steam, and carry an ever-varying weight of cargo besides, the difference is material. Setting, however, these circumstances aside, Mr. Clifford quite overlooks the chief drift of my argument, namely, that a ship when pressed by canvas may have a considerable heel at the time it is necessary to lower a boat from one side or the other; the weather boat will consequently be raised several feet higher from the water's edge than the opposite one; it is hardly necessary to add that no adjustment of pendants could be adapted to meet these ever-fluctuating changes during a sea voyage.

Again, I am asked with reference to the old plan of lowering with tackles which Captain Kynaston still thinks it advisable to retain—"What is to prevent one fall going by a run?" I may put a similar question—What is to prevent one of Mr. Clifford's "single pendants," which may work stiffly in the nip-sheaves, from going with a surge, and producing the same ill effects which the designer professes to avoid? It is true that both pendants being reeled upon the same cylinder will be released from it simultaneously; it does not, however, follow that they should traverse with the same facility through the sheaves, for the reason thus mentioned; one or the other may work stiffly for a while, and then become released with a surge, either carrying away with the jerk, or causing the boat to descend unevenly to the water's edge, as was fully exemplified in the last trial of the Exmouth, when the engines were stopped to avoid an accident. Mr. Clifford having desired me to produce an instance of a serious accident through the above cause, I am bound to give one. A few months ago Her Majesty's ship Renown was leading the line of the Channel squadron into Plymouth Sound, when a false alarm of a man overboard was raised; on this a crew jumped into one of the cutters, and a man had already commenced to lower, when one of the pendants broke with a surge, and the crew, gear, &c., were precipitated into the water, carrying away one of the davits at the same time; to remedy the disaster the opposite boat was ordered to be lowered, and, strange to say, precisely the same accident occurred, the davit, however, remaining entire.

With reference to another remark in Mr.

Clifford's letter, I certainly cannot view it as an objection to Captain Kynaston's method of disengaging, when there are probably no less than twelve men sitting idle in a boat, that one among their number should be told off to let go a rope in case of need, which acts as a reserve, or a safety trigger, to meet the remote contingency of the proper disengaging line being foul, and therefore may be the means of preserving life; in short, having, as it were, two strings to his bow, is a manifest advantage, and I think Mr. Clifford will do well to consider this; for if his boats, as now fitted, be lowered from a vessel going at any speed, and one of the pendants be jammed, the crew have no immediate resource to save themselves from the imminent risk of destruction. Having made distant allusion to a catastrophe of this kind, and been called upon by Mr. Clifford to substantiate my statement, I will do so, though with some reluctance. In May last a written document came into my hand, which I have quoted word for word—"The ship Orwell, belonging to Messrs. Green, of London, had a boat fitted with 'Clifford's lowering apparatus.' In lowering the boat to pick up a man overboard, the fore-pendant hung when the boat was at the water's edge, and swamped her, drowning all her crew; this occurred on her last voyage to Australia." Every one would be glad to find this deplorable event contradicted, but unfortunately I have it corroborated also in writing on the testimony of Mr. Green's own officers by the hand of one of Mr. Clifford's staunchest allies, and I think it a pity, therefore, that the former should put himself so much out of his way to challenge or deny the truth of a statement which I fear does not admit of the shadow of a doubt, the more so that it is not in human nature that our best efforts should be infallible, and that Mr. Clifford's plan has been already instrumental in saving life.

To avoid similar disasters I certainly would not advise Mr. Clifford to practise the dangerous experiment for which, he says, his plan is so well adapted, that of attempting to drop his boat on the top of a wave which he may encounter during his descent, or during the roll of a ship; however free may be the working condition of his pendants round the roller and through their respective sheaves, it must be a sluggish wave indeed, or the ship must be an easy roller, whose rising or falling motion does not surpass the descent of a boat released under such circumstances by the lowering rope being let go—she will probably drop into the trough of the sea in any case, or if a pendant hangs or is carried away, a catastrophe will be inevitable. Captain Kynaston, whose mode of disengaging is instantaneous, and in the power of one man in the boat, and (contrary to Mr. Clifford's statement) perfectly independent of those who are lowering by the tackles, might probably practise this feat with impunity.

I do not consider Mr. Clifford is borne out in his statement, which attributes the fragility of some of his pendants to the neglect of any one particular dockyard; I believe never was invention more zealously and carefully worked out by our Dockyard executives. It must be borne in mind that a man-of-war has her boats in constant use, whereas emigrant and transport ships have seldom any occasion whatever to lower them; if, therefore, as Mr. Clifford states, no reports have reached their owners of broken gear, &c., the inventor has reason to rejoice, but the public at large will not receive the fact as a proof of the infallibility of his plan or the durability of his pendants.

In conclusion, I will add that the test of time is alone able to establish the merits of every plan, and in the meantime there is no reason in the world why two methods of saving life, which have already given proof of their efficiency, should not jog along amicably together, and not jostle each other like the two pitchers in the stream, in the hope of one becoming irretrievably smashed. There is surely room enough for both, and there are ships enough on the ocean with their living freights whose owners should gladly

receive every invention which may tend to diminish the loss of human life.

I remain, Gentlemen, your obedient servant,
 NAUTICUS.

July 2nd, 1859.

APPLICATION OF ARTIFICIAL LIGHT IN PHOTOGRAPHY.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—Permit me through the medium of your columns to suggest an improvement in the use of artificial light in photographic operations—a subject which appears to be attracting much attention at present.

It is well-known that when solar light is analysed by the prism it is found that not only are the three primary colours which compose white light arranged in different proportions in different parts of the spectrum, so as to produce a great variety of colours, but that the three principles existing in the rays of the sun—light, heat, and actinism—are likewise each of them distributed unequally over the spectrum, appearing in greater intensity in some parts than others, so that each colour is combined with a definite proportion of each of the three principles. The red rays are the greatest heating power; the lightest colour is the yellow; while the blue rays are the most definite in both heating and illuminative powers, but are by far the richest in actinic or photographic power. This law prevails equally in colours obtained from sources other than the solar spectrum, and is applied practically in many of the operations of daily life. Thus in artificial illumination, we select substances which by their combustion emit a large proportion of yellow light; and when we wish to diminish to the greatest extent the apparent light of a luminous object, the sun, for example, we observe it through the medium of a blue glass. In warming or apartments we make use of coals, &c., which by their burning give a red light, the characteristic property of which is, that it contains a very great amount of radiant heat, with but a comparatively small proportion of illuminative power (indeed the appearance of a red object invariably conveys to the mind a sensation of warmth). The single exception is in the selection of sources of artificial light for photographic purposes. In this case the object aimed at seems to be the production of a light of the greatest possible whiteness and intensity. But the blue rays, and especially the violet, possess the greatest proportion of the photographic principle, and are at the same time the most deficient in heating and illuminative power, while the red and yellow rays are almost entirely destitute of the photographic principle. And it is evidently this principle alone which is of service in a photographic operation, the others—the light especially—being an evil rather than otherwise if the object in view be the production of a portrait, for the inconvenience and discomfort experienced by the sitter in consequence of too great an intensity of light almost invariably occasions distortion of the features. Why, then, is not a blue or a violet light made use of? Such a light would be extremely powerful as a photographic agent, while its low illuminative and heating power would admit of its being used in a very high degree of intensity without creating discomfort to the eyes of either sitter or operator. It would doubtless be a very difficult task to discover a composition which would burn with a pure and intense violet light.

I have not had the opportunity of investigating the subject practically, and I am therefore indebted to place it before your readers in the hope that the suggestion may receive the consideration of any one who may think it worth his while to pursue the subject further. In case the idea should not be a new one, I hope that my ignorance of such a fact will prove a sufficient excuse.

My attention was first drawn to the subject by a lecture illustrative of Moule's method of obtaining photographs by artificial light, in which a light of great whiteness and intensity is produced by the combustion of a chemical composite; but I observed that the great intensity of the light

necessitated the interposition of a screen between the light and the face of the sifter, who afterwards remarked that the light was even with this precaution very oppressive.

Your obedient servant,

FRANCIS H. BAKER.

Inland Revenue, Somerset House,
20th June, 1859.

THE ARMSTRONG GUN.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—As my son, Dr. H. Drake, has considered it right to call your attention to the gun known by the name of the "Armstrong gun," I beg to request the favour of being permitted to offer a few remarks on the subject.

In your number 1779, of Saturday, September 13th, 1857, a letter appeared from me in explanation of the difficulties we had to contend with at Woolwich relative to this and a number of guns brought under discussion by official authority, before Sir William Armstrong by his own statement, to which Dr. Drake calls attention, had undertaken to propose the one in question; consequently, I will not occupy your space beyond necessity, in further explanation of those difficulties.

Having so far made public the origin of his invention, I should advise Dr. Drake to hand you for publication a drawing in detail, as it will at once show the inventions to be one and the same in every respect—*even to the forging*—with the exception of the Swedish process of preventing the escape of gas introduced in the Armstrong gun, but not so simple or effective as that previously submitted.

As my son had visited Woolwich three times at a considerable disadvantage, I did not consider it advisable to trouble him with the description of the Armstrong gun when professionally made known to me in the early part of December; at the same time I was not unmindful of my duty in obtaining the originality of the invention "instantly" at the War Department and Horse Guards; and I requested Major General Peel to allow me to place before him the manuscript invention, which he declined to inspect or allow it to be inspected by any one in his confidence at the War Office.

I then proposed to place it in the hands of a committee of professional gentlemen, and named Sir Charles Fox, Mr. William Fairbairn, Mr. Thomas Howard, and Mr. James Nasmyth, or any others whom the Secretary at War might suggest, with permission to pay all expenses out of any award which those gentlemen might consider due under the circumstance of Dr. Drake having officially submitted his gun to the select committee before Sir William Armstrong, but which was also refused; and this, it must be understood, was before the Secretary at War had ordered it to be adopted in Her Majesty's service.

I have the honour to be, Gentlemen,

Your obedient humble servant,

JOHN POAD DRAKE.

London, June 22nd.

THE GREAT EASTERN.

GENTLEMEN,—All those who feel anxious for the success of such a gigantic structure as this vessel presents, naturally ask the question if the best ways and means are being employed to produce such a result? As regards the propelling means, such is most certainly not the case; in the first place, the employment of paddle-wheels destroys her usefulness as a sailing vessel; which is the more to be regretted, as a ship of her size and structure might be expected to realize a speed beyond that ever obtained. Her screw is not provided with any means of raising it out of the water; and that if the engine is at fault, or any cause prevents its employment, it must be dragged on yards at a great loss of speed; if anything fouls or injures it, there is not any remedy, as the difficulties of examination, without a trunk over the crew, and proper means of lifting, are necessarily increased from her size. Having two dis-

inct propelling means, it necessarily offers the opportunity of using either separately, but from what has been shown, it has evidently not been made available in this case.

A READER.

LORD CARLINGFORD ON THE GRIFFITH'S SCREW.

VISCOUNT CARLINGFORD requests us to give place to the following letters, addressed originally to the editor of the *Engineer*. Our contemporary doubtless had his own sufficient reasons for rejecting them, but as these reasons do not appear to us, and as we see nothing particularly objectionable in the letters, we willingly insert them, particularly as Lord Carlingford deems their insertion of importance to his claims as an inventor.

GENTLEMEN,—As a matter of justice I must beg leave to request you will give publicity to the letter I addressed to you previous to your publication of the 10th inst.* for I cannot submit to the insidious manner of attempting to supersede my discovery of the true principle of the screw propeller, which I presented to the country and the world, and which has caused a revolution in navigation, and has all but put down the paddle-wheels, except on rivers. The public know its value, and I will not allow any person to attempt to rob me of the honour of having discovered it without protesting against them. In your article on the subject you say, "The spherical boss, which is one of the distinctive features of the Griffith propeller," this may be the case, but it is also the case with the Carlingford screw, and to which I afterwards added a horn in continuation, to be used when required to be placed in front; so that the spherical boss is no novelty whatever, nor would the hour-glass shape of boss be either a novelty, while the contrivance to alter the pitch proves a total ignorance of the principle of the screw altogether, as described in my letter above referred to. So the mere cutting of the corners of the screw which I have done long since, and the mere increase of size of the screw towards the centre cannot constitute a right to a patent, for that does not touch in the slightest degree the real principle of the screw, which must be for ever adhered to whatever increase or alteration is given to its edge or size at any part. I cannot admit the correctness of your remark in reply to my letter, "that Mr. Griffith condemns the whole family of the feathering screws," when he claims the improvement of making the ends of his screw more feathered by clipping off the corners. The account I read in the papers distinctly states that the invention principally consists in the power of altering the pitch. Now the clipping of the corners is merely to obtain a sharper or more obtuse angle to the edges of the blades, and it is done at the sacrifice of part of the most effective part of the screw, but which can be better obtained by giving the edges the fish-bone or saw form to proceed through the water and leave it, which is without exception the principle of nature. I therefore repeat, and request as a point of justice, that you will publish my letter here referred to, as well as this one, for of course the only object for the public is to know the truth, and the entire truth. These attempts to deprive me of the honour of my discovery remind me of the fable of Florian, where the butterfly is envied for his wings, yet the clipping of the corners will not destroy them.

I remain, gentlemen,

Your obedient servant,

CARLINGFORD.

Swift's Heath, Kilkenny, June 18, 1859.

GENTLEMEN,—If you refer to my last letter you will perceive that you are mistaken in saying that I claim the invention of the spherical boss, one of so little consequence; I merely said that I adopted that form as well as I did others; many persons may have done so before me. I only stated my having given it that form to show it was no novelty, and such also appears from your statement. Then, I ask, what novelty or what improvement has Mr. Griffith made for which he proposes taking a patent? I can only see the adjustable pitch, which, as I before stated to you, proves a total ignorance of the principle of the screw. It is not possible that he means to take

* The letter in question states that any alteration of the pitch of the screw must destroy at once the required proportion of pitch, as of course it would be diverted at the centre as much as at the extremities; the due proportion of pitch would consequently be lost, for it should be diverted six times more at the extremities, which would be impossible to accomplish, and at the same time give firmness to the screw, and even if accomplished of no use whatever.

a patent for cutting off the corners of the Carlingford screw; but it is neither for the spherical boss, for that is only required when the part of the vessel where it is applied is not wide or large enough to cover its front centre, to prevent that part from presenting a flat surface to the water; nor is it the edges of the screw that is of so much importance, but that which is of importance, and for which I claim the discovery of the screw now universally adopted, is that of the proportion of pitch from the extremity to its centre, which I discovered should be one-sixth taken from its centre line, which you published for me, and the problem of which you submitted for me to the scientific world. All the other details are not worth noticing, being very trivial to the real discovery, which has re-established confidence in the screw-propeller, that had been totally lost up to the very time I presented my discovery to the Admiralty; but I consider this manner of giving insidious replies to my letters, instead of inserting them, to be very unfair, leaving erroneous impressions of that which I had stated; but first insert them, and then reply whatever you please. I must still insist that the principle of "The Griffith Screw," which I read the account of, was experimented principally on its different variations of pitch, first on one pitch, then on a sharper pitch, and finally to be tried on a medium pitch; this every person can see on referring to the report; but I say again publish my letters, and they will speak for themselves, they are scientific, and explain the true principle of the screw-propeller, which has done wonders, and yet is still very little understood, as seen by the account given of the late trials with "The Griffith Screw."

I remain, gentlemen,

Your obedient servant,

CARLINGFORD.

Swift's Heath, Kilkenny, 27th June, 1859.

Proceedings of Societies.

ROYAL AGRICULTURAL OF ENGLAND.

June 20.—At a weekly council held this day, Co-Challoner, Trustees, in the chair, the names of candid dates for election were read. Dr. Voelcker submitted to the Council an analysis of a Mangel Wurzel which was grown in 1857, and has been kept for nearly two years in an apparently sound condition. A communication was read by Mr. Charles Fulbrook, of Dallington, Hurst Green, giving the result of his investigations of the laws governing the wet and dry seasons occasionally experienced in this country. On the motion of Lord Feversham, seconded by the Hon. Wm. Cavendish, this communication was referred to the Journal Committee, and the thanks of the Council were ordered to be conveyed to Mr. Fulbrook. M. Tisserand, Inspector of the Imperial Farms of France, transmitted to the Council programmes of the special international competition of reaping machines, to take place at the Imperial Farm of Foulleuse, near St. Cloud, between July 20th and 26th next. The certificates of entry to be sent by exhibitors to his Excellency the Minister of Agriculture, 78 bis, Rue de Varennes, Paris, on or before July 10th. The following communications were also received from Mr. Chas. W. Hamilton: a Schedule of Queries issued by the Royal Dublin Society respecting the Condition of Farm Labourers; the Journal of the Agricultural Society of Alger, and the Journal of the Central Agricultural Society of Belgium, for all of which the thanks of the Council were ordered. Mr. H. Tucker, from the New York States Agricultural Society, presented a letter deputing him to attend on behalf of that Society at the Warwick Show. The Chairman assured Mr. Tucker that the officers of the Society would afford him every facility in their power to enable him to inspect the trials and general exhibition.

THE GEOLOGICAL SOCIETY OF LONDON.

June 22.—Sir C. Lyell, Vice-President, in the Chair. *Adjourned Meeting*.—The following communications were read:—1. "Further Observations on the Ossiferous Caves near Palermo." By Dr. Falconer, F.R.S., V.P.G.S. 2. Mr. Prestwich gave in a few words the results of the examination of the bone-cave at Brixham in Devonshire. 3. "Observations on a Flint-implement recently discovered in a bed of Gravel at Saint-Acheul, near Amiens." By John Wickham Flower, Esq. (Communicated by Joseph Prestwich, Esq., F.G.S.) The gravel capping a slight elevation of the chalk at St. Acheul is composed of water-worn chalk-flints, and is about 10 feet thick; above it is a thin band of sand, surmounted by sandy beds (3 feet 6 in.), and brick-earth (11 feet 9 in.) In this gravel the remains of elephant, horse, and deer have been

found, with land and fresh-water shells of recent species. From the gravel Mr. Flower dug out a flint- implement, shaped like a spear-head, at about 18 inches from the face of the pit, and 16 feet from the surface of the ground. Mr. Flower in this communication pointed out evidences to prove that this and many other similar flint-implements obtained from the same gravel were really the result of human manufacture, and not the previous to the deposition of the gravel in its present place. Mr. Flower's visit to St. Acheul was made in company with Messrs. Prestwich, Godwin-Austen, and Mylne, with a view to verify the discoveries made respecting the occurrence of flint-implements in the gravels and peat of the Somme Valley by M. Boucher de Perthes, of Amiens. [A large collection of Osseous remains and Flint-objects from the Grotto di Macagnone, and others from San Ciro were exhibited; also specimens of Flint-objects from Brisham Cave, the gravel of Amiens, &c., and a series of Flint-implements from Arabia, North America, Mexico, &c.] The next meeting of the Society will be held November 2nd, 1869.

ROYAL GEOGRAPHICAL SOCIETY.

The closing meeting of the Session of this Society, numerously attended, was held on Monday evening at Burlington House; the Earl of Ripon, President, in the chair. *Presentations*.—S. W. Silver and Christian Hellmann, Esqs., were presented upon their election. *Elections*.—The Duke of Newcastle, the Earl of Elgin and Airlie, the Hon. Robert Marsham, Sir Hercules G. R. Robinson (Governor of Hong Kong), Major Henry Cracroft, Captain Phillip D. Margesson, R.A., George Barclay, Frederick W. Digge, H. Austin Bruce, M.P., R. A. Osborn Dalryell (Consul at Erzerum), George Fitzroy, William Fryer, Charles P. Grenfell, M.P., W. Vernon Harcourt, and William H. Smith, Esqs., were elected Fellows. *Proposals*.—Professor Otto Struve, of St. Petersburg, as a corresponding member; Lord Henry Scott, Sir Edward Brough, Bart., the Rev. Charles Oakley, M.A., Henry Duckworth, George Gamble, Charles Marrett, M.A., and Francis Tagart, Esqs., were proposed as candidates for election. *Exhibitions*.—Several drawings and photo-lithographs illustrating the scenery and physical geography of the highest parts of the Himalayas, by the Messrs. Schlagintweit; and a mechanical and magnetic Compass, invented by Mr. Maillard, were exhibited to the meeting. *Accessions*.—Sir John Rennie's work on the "Plymouth Breakwater," presented by the author; Humboldt's "Travels," "Cosmos," and "Aspects of Nature," presented by H. G. Bohn, Esq., F.R.G.S.; Dr. Lange's map of the Mediterranean, and Stanford's library map of Australasia, were among the late accessions to the Library and Map-rooms. The papers read were:—1. Notes on a Voyage to New Guinea, by Alfred R. Wallace, Esq., F.R.G.S. 2. Remarks on Portuguese Journeys in Central Africa, by James Macqueen, Esq., F.R.G.S. After some observations from Captain Burton in reply to Mr. Macqueen, Major Palmer, F.R.G.S., read: 3. Notes on the Island of St. Helena, to accompany his new map of that island. At the suggestion of Sir Roderick Murchison, who introduced them with allusions to their travels, one of the brothers Schlagintweit offered remarks in explanation of their drawings in the Himalayas; and the President having proposed a vote of thanks to the authorities of the University of London and of the Royal Society for the use of their large hall during the past session, the meeting adjourned to November 14.

ASSOCIATION OF FOREMEN ENGINEERS.

July 2.—The usual monthly meeting of the Association of Foremen Engineers took place at their temporary rooms in the City. Mr. Joseph Newton presided over a large assemblage of members, drawn together by the announcement previously made that Mr. Stabler would read a paper on the "Economical Formation of Steam."

The business of the evening commenced with the bringing up of the auditors' report for the half-year past, and its reception by vote on the part of the associates. Four committee-men were also elected in place of those who retired by rotation, and this, with some minor matters, brought 9 o'clock—the appointed hour for lectures and paper-reading, and when the friends of members are also admitted. Mr. Newton having now called upon Mr. Stabler to proceed with his task, at once commenced it. He said, in reviewing the numerous contrivances for the cheap generation of steam which had followed the wondrous inventions of Watt and of those unrecognised great men who quietly assisted him in his study and in his workshop—that so far as the character and properties of steam were concerned, little had been discovered that was not known to Watt himself. His rules and data, to a

considerable extent, were the surest guides to mechanical men of to-day. The forms of boilers, areas of fire-grate, and perfect and imperfect combustion of fuel, occupied much of Mr. Stabler's paper. His conclusions being that the "economical formation of steam" depends on perfect combustion, and the absorbing and transmitting powers of boilers. Combustion might be perfect, but the absorption of a boiler might be inferior, and then the evaporation of water would be at a low rate as compared with the consumption of fuel. To construct a boiler with rapidly-absorbing materials was one of the great principles aimed at by the engineers of our time.

Mr. Stabler spoke of the proportions necessary for boilers of marine, stationary, and locomotive engines, and ended his remarks by inviting his brother members to think out for themselves the great question of steam economy, upon which wide differences of opinion still existed.

A discussion followed, in which Messrs. Aydon, Briggs, and others joined; and after a vote of thanks to Mr. Stabler had been unanimously given, and an announcement made of Mr. Galloway's intention to read a paper at the August meeting on "The Superheating of Steam," Mr. Newton declared the meeting to be dissolved.

Our Weekly Gossip.

It is a singular fact that in giving the return of coinage executed during the year 1858, almost all our contemporaries, from the *Times* downwards, fell into error as to the quantities of pence, halfpence, and farthings produced at the Mint. Reference to the columns of last week's *MECHANICS' MAGAZINE* will enable the public to correct that error. In examining the Government report on the subject, it is evident that other journals have mistaken the number of pounds in value of copper coins struck, for the number of pieces produced, a circumstance which of course makes their statistics inaccurate, to the extent of several millions of coins.

The directors of the Great Northern Railway having consented, from the 1st of July last, to allow the produce of the various South Yorkshire Collieries to be sold with the name of the colliery, and unmixed with any other coal, the owners of the best coal naturally regarded this as a very great advantage, and resolved to celebrate this separation of qualities by conveying to their collieries and back eight hundred members of the press, the London coal trade, and others, in order to afford them an opportunity of seeing the source of supply and the mode of working the coal in the pit. Of this arrangement we availed ourselves on Wednesday last, proceeding from town early in the morning, and visiting the Lund Hill, the Edmund Main, and the Oaks collieries, returning to town via Doncaster in the evening. The Lund Hill colliery we descended, (the depth being 680 feet) and had the very doubtful satisfaction of marching, Davy in hand, through some mile or two of passages, mainly of about three feet in height. As our pace was somewhat rapid, and as it had to be kept up while we were doubled down into the dwarfish height of, say, 40 inches, we did not find the visit particularly exhilarating. We subsequently descended the Edmund Main, however, but finding the shaft wetter than was agreeable, we declined entering upon further subterranean exploration, and allowed ourselves to be run up to the sunshine again. Another short trip next carried us to the Oaks, the splendid winding engine of which attracted all our attention; and a still further trip delivered us at Barnsley, where welcome ablutions and other creature comforts were happily procured. Here Mr. Carter, of the well-known firm of Carter, Brothers, gave us a run through their extensive linen fabric factory, in which we were so fortunate as to find in operation a loom which will make a fabric no less than five yards wide—the largest loom of the kind in the world, we believe. The shuttle seems fairly to tire in crossing it. We must not omit to state that Mr. Plimsoll, junr., of the King's Cross Station, managed the whole trip with exemplary skill and suavity, and as the merits of the South Yorkshire coal, both as a steam coal, a gas coal, and a house coal—different kinds, of course—seemed to impress many of the visitors, we doubt not he will find his anxiety and urbanity rewarded.

In his speech at the anniversary dinner of the Society of Arts, held last week, the Chairman of Council (Mr. C. Wentworth Dilke), afforded some useful information respecting the proposed Exhibition of 1861. From his remarks, it appears that the project for that Exhibition was not stopped. Circumstances over which they had no control had unhappily produced continental war; but he ventured to say that the proposed Exhibition was simply postponed.

He had no hesitation in declaring that but for the war everything was prepared and success was certain. A guarantee fund to the amount of £250,000 was so far advanced that he felt certain it would have been completed immediately after the list had been made public. Therefore, whenever peace should be happily declared, he trusted that whoever might be in power in the Society—for his term of office expired on the following day—would bring forward this movement again, and that in 1862 or 1863 they would have a Universal Exhibition, which would be equally if not more successful than that of 1861.

The Emperor Napoleon is making free (and fair) use of balloons in his operations against the Austrian armies in Italy. This fact has called forth a letter from Mr. Coxwell (to whom we made reference a few weeks since*), in which he says:—"Ever since the Russian war, and, indeed, during that calamity, I have laboured single-handed in endeavouring to provoke the attention of our Government, our scientific men, and the English press to the importance of aerial observatories. As the idea just begins to engage public notice at the present moment, it may not be uninteresting to simply correct one or two erroneous notions as to the *modus operandi* with war balloons. In the *Aërostatic Magazine* for this year I devote a chapter to 'Balloons for Reconnoitring,' but as extracts may be too lengthy I will briefly observe: that balloons may be used with long wire ropes attached (kite fashion) without being let go, which might endanger their falling in an enemy's camp. 2. There is no real necessity that the balloon should be within close range of large or small shot, as an angle of elevation proportioned to the distance would afford the required information. 3. Hydrogen gas, generated by the decomposition of water, would enable balloons to be inflated in whatever locality desirable. Balloons may also be made the vehicles of laying a temporary electric wire or thread in any direction required. A large revolving drum beneath the car might contain many miles of thin wire, and pay it out as desired. Certain indications would be required to mark its course, but this could be easily managed. In this way a network of electrical communication might be established. Like spiders the balloon could spin away in various directions, and if one part of the web gave way the main lines might be depended upon to convey intelligence."

The following Minute has been recently passed by the Committee of Council on Education:—"My Lords proceed to revise the Minutes which have been passed in the Science and Art Department for the encouragement of scientific instruction among the industrial classes of this country who have already received primary education. I. All former Minutes relating to Science or Trade Schools, and Scientific class instruction, except those referring to Navigation, Public Lectures, and the training of Teachers (as hereafter appended), are hereby cancelled, and the following regulations are substituted in their place. II. The Science and Art Department will hereafter assist the industrial classes of this country in supplying themselves with instruction in the rudiments of—1. Practical and Descriptive Geometry, with Mechanical and Machine Drawing and Building Construction; 2. Physics; 3. Chemistry; 4. Geology and Mineralogy (applied to Mining); 5. Natural History, in augmentation grants in aid of salary to competent Teachers, and by payments and prizes on successful results, and grants for apparatus, etc. III. Any School or Science Class either existing or about to be established and duly approved by the Science and Art Department, may apply, through its Managers, for a *Certificated Teacher*, or for the certification of any Teacher, in any one or more of the above-named branches of Science IV. Examinations for certificates of three grades of competency to teach any of the above-named Sciences will be held annually by the Department, in the last week of November, in the Metropolis, as follows:—Nos. 1, 2, and 5 at South Kensington; No. 3 at the Royal College of Chemistry, Oxford-street; No. 4 at the School of Mines, Jermyn-street. V. Annus grants, in augmentation of salaries of Teachers so certified to teach in any of the above-mentioned Sciences, will be given as follows:—For the 1st grade of competency, £20; for the 2nd grade of competency, £5; for the 3rd grade of competency, £10. Any Teacher holding a certificate of competency to give primary instruction will receive, from the Science and Art Department, a sum equal to the augmentation grant which has been attached to such certificate, in addition to the grants above-mentioned. VI. Such grants will only be made while the Teacher is giving instruction in a School or Science Class for the industrial classes, approved by the Department. VII. The Department will require that suitable premises shall be found and

maintained at the cost of the locality where the School or Class is held; that the names of ten students shall be entered whose fees for half a year shall have been paid in advance; and that the local Managers shall guarantee, for the support of the Schools and Teachers, from fees or local funds, a sum at least equal to the grants so long as they shall be paid. If at any time neither fees of pupils nor local funds cover the requisite amount, it must be inferred that there is no demand for instruction in the above-named Sciences in that locality, which the Government is justified in aiding; and the assistance of the Department will be withdrawn. VIII. Every School or Class having a certified teacher will be inspected and examined once a year by the Department, and Queen's prizes of an honorary kind will be awarded to successful students. IX. Payments will be made to the teacher on each first-class Queen's prize obtained by the student, £3; on each second-class, £2; and on each third-class, £1. X. A grant towards the purchase of apparatus, fittings, diagrams, etc., of 50 per cent. on the cost of them, will continue to be afforded to Schools and Classes in Mechanics' and similar Institutions.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgement:—

STEAM ENGINES, &c., 2674, 2686, 2693, 2706, 2711, 2717.
BOILERS AND THEIR FURNACES, 2641, 2656, 2658.
ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 2646, 2701, 2709, 2710.
SHIPS AND BOATS, including their fittings, 2640, 2651, 2671, 2690.
CULTIVATION OF THE SOIL, including agricultural and horticultural implements and machines, *None*.
FOOD AND BEVERAGES, including apparatus for preparing food for men and animals, 2652, 2665.
FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 2647, 2654, 2657, 2661, 2677, 2679, 2684, 2691, 2694, 2697, 2698, 2704, 2715, 2720.
BUILDINGS AND BUILDING MATERIALS, including sewers, drains, pipes, brick and tile machines, &c., 2642, 2643, 2675.
LIGHTING, HEATING, AND VENTILATING, 2636, 2662, 2669, 2673, 2680, 2682, 2705.
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 2642, 2676, 2678, 2683, 2687, 2703, 2718.
METALS, including apparatus for their manufacture, 2700.
CHEMISTRY AND PHOTOGRAPHY, 2644, 2649, 2667, 2682, 2706.
ELECTRIC APPARATUS, 2670, 2714.
WARFARE, 2664, 2668.
LETTER PRESS PRINTING &c. *None*.
MISCELLANEOUS, 2645, 2648, 2650, 2653, 2655, 2680, 2663, 2666, 2667, 2672, 2677, 2678, 2681, 2682, 2685, 2688, 2689, 2690, 2696, 2694, 2695, 2696, 2702, 2707, 2709, 2712, 2713, 2715, 2716, 2719.

2640. H. JORDAN. *Improvements applicable to navigable vessels.* Dated November 20, 1858.

This comprises various novel features in the build and rig of iron and wooden ships, the details of which are too voluminous to find space in our pages. *Patent completed.*

2641. D. EVANS. *Improvements in tubular steam-boilers and fire-places or furnaces used therewith.* Dated November 20, 1858.

In constructing a tubular steam-boiler, the patentee forms across the fire-box a horizontal or somewhat inclined water-chamber, open to the sides of the fire-box and also to the body of the boiler. Through this water-chamber numerous tubes pass, the ends of which are respectively fixed in the upper and lower plates of the chamber. The upper surface of the chamber is to receive the fuel, and the draft is caused to pass down through the fuel and down through the tubes into a chamber below, and thence the products of combustion pass through numerous horizontal, inclined, or upright tubes through the body of the boiler into the chimney. To heat water in a separate tank, or in the tender of a locomotive engine, an arrangement of hollow or tubular fire-bars is used. *Patent completed.*

2642. L. PRECIVAL and J. HOUGHTON. *Improvements in attaching knobs of glass, china, and earthenware, to the spindles of locks and latches, and to drawers and other articles.* Dated November 20, 1858.

The inventors make that part of the spindle which enters the knob of any other than a cylindrical form. A screw passed from the front of the knob engages in the end of the spindle, and fixes the knob thereon. A washer and socket may be put on to the spindle between the shoulder of the knob and the lock or latch to prevent friction of the shoulder of the knob against the door. There is also an arrangement for attaching knobs when rotary motion in the knob is not required. *Patent abandoned.*

2643. J. YOUNG. *Improvements in fastenings for window sashes and casements, and in chain used in suspending.* Dated November 20, 1858.

This consists, 1, in applying locking mechanism to

window sashes, &c.; 2, in making chain for suspending window sashes, &c.; of alternate cast, single links, and wrought or stamped, double links, the said links being joined together by pins. *Patent completed.*

2644. H. SWAN. *Improvements in stereoscopes and other optical instruments, and in stands or supports for stereoscopes.* Dated November 20, 1858.

In arranging stereoscopes, the standard, which connects the stage of the instrument with the frame in which the glasses are fixed, is divided transversely into two parts, and in one of these parts two projecting wires or prongs are fixed and these enter corresponding holes in the other part. The holes are lined with cloth so that sufficient friction may be offered to the sliding of the prongs in the holes to retain them in any position in which they may be placed. When the instrument is in use it is held by a button attached to the lower part of the standard, and the adjustment of the distance between the picture and the glasses is effected by placing the end of the thumb in a recess formed in the upper portion of the standard, moving it up or down till the proper distance is found. The portions of the standard may be either rigidly fixed to the stage and to the frame of the glasses, or may be attached by hinges furnished with springs similar to the springs of a pocket knife. There are other arrangements included. *Patent abandoned.*

2645. H. BODEN and T. COOPER. *Improvements in plating or braiding machinery.* Dated November 20, 1858.

Provisional protection has not been granted for this invention. *Patent abandoned.*

2646. H. GARDINER. *Improvements in the compound axle hub and wheel for railroad cars.* Dated Nov. 20, 1858.

This consists, 1, in having the joints of the compound axle within the hub and within the line of pressure upon the wheel, and in constructing and arranging the parts constituting the hub in connection with a cylindrical sleeve or case (also within the hub) over the joint, so as to hold the parts together with sufficient strength, and so as to permit the wheels to turn independently of each other and of the main part of the axle, and for the most part to permit the two wheels and the whole compound axle to make their rotation together. 2, in constructing the hub and combining the parts of the hub and the plates so that the wheel plates are set into a mortice between the rings constituting the sections of the hub, while the exterior or edges of the wheel plates are upset so as to secure and hold the tyre very firmly. 3, in adapting a wheel constructed of a solid hub to the compound axle with the joint within the hub. *Patent completed.*

2647. C. H. MELLOR. *An improved manufacture of woven fabrics.* Dated November 22, 1858.

This consists in combining honeycomb weaving with plain, twilled, fancy, or double weaving. *Patent abandoned.*

2648. R. NELSON. *Improvements in apparatus for raising and lifting water and other liquids.* Dated November 22, 1858.

Here the patentee obtains a vacuum by the ignition of heated hydro-carbon fluids, such as turpentine, naphtha, and alcohol. The invention is not described apart from the drawings. *Patent completed.*

2649. F. A. THEROUDE. *Improvements in obtaining salts and products from the ashes of marine plants.* Dated November 22, 1858.

Here a concentrated solution is prepared from the ashes by causing successive quantities of water to pass through successive layers of ash. *Patent completed.*

2650. S. W. JOHNSON and J. VARLEY. *Improvements in pressure and vacuum gauges.* Dated November 22, 1858.

This invention was described and illustrated at page 74 of the MECHANICS' MAGAZINE. (New Series.) *Patent completed.*

2651. A. V. NEWTON. *Improved apparatus for propelling and steering vessels.* (A communication.) Dated November 22, 1858.

The object here is to effect the steering of the vessel by the propeller itself, the axis of which is made moveable for the purpose. *Patent completed.*

2652. E. H. BENTALL. *An improvement in the construction of turnip-cutters.* Dated November 22, 1858.

This relates to a method of discharging the dirt and the chips made in turnip-cutters so that they may be collected separately from the other and clean portions of the cut root or turnip. The invention applies chiefly to the gardener or barrel turnip-cutter, and consists in providing it with an additional spout or discharge to receive and convey away those portions of the root that do not pass through the knives, and find their way into the barrel, but lie outside the barrel until they are discharged. *Patent completed.*

2653. T. SPENCER. *Improvements in the manufacture or construction of springs.* Dated November 22, 1858.

This relates, 1, to "Baillies" volute springs, and consists in forming the coils with ribs or projections upon them for strengthening the coils and preventing them from pressing or rubbing their whole surface upon each other when the spring is being compressed. It relates, 2, to laminated springs, and consists in dispensing with the slits and studs, or ribs, by forming at the ends of the plates small hollow ribs or projections, the underside, or cavity, formed in making these ribs upon the upper plates fitting upon the ribs or projections upon the under plates or vice versa. *Patent completed.*

2654. W. RALSTON. *Improvements in embossing and finishing woven fabrics, and in the machinery or apparatus employed therein.* Dated November 23, 1858.

The patentee employs a roller of wood or metal, and grooves or indents upon it any desired design, and causes it to revolve with a bowl or bowls of paper, &c. He gives the circumference of the pattern roller a quicker motion than the circumference of one of the bowls, so as to obtain a frictional action upon the surface of the fabric as well as pressure, so that if the fabric is moved transversely when fed to the machine, an indefinite number of watering patterns may be given to the fabric at one operation or passage; but if two operations be given, more antique or

other varieties may be obtained, which can be still further varied as desired, according to the number of times the fabric is allowed to pass through the machine. A bright finish or lustre is given to the fabric by the rubbing action of the two surfaces of the roller and bowl. *Patent completed.*

2655. W. H. DAWES. *An improvement in forge hammers, and in the anvils used with forge hammers and squeezers.* Dated Nov. 23, 1858.

Here the patentee makes a series of channels or passages in the tools of the said hammers and anvils, the chambers, &c., being made in a plane parallel to that of the working surface, and as near the surface as possible. By causing water to circulate through the channels, &c., the forge hammer and anvils are kept cool. *Patent completed.*

2656. W. GORMAN. *Improvements in furnaces and in the combustion of fuel, and in apparatus connected therewith.* Dated Nov. 23, 1858.

This relates to a process of burning gaseous fuel in draught furnaces, such as are usually employed for generating steam in steam boilers, and consists in preventing air from getting up through the incandescent or highly-heated coke lying on the grate bars when a fresh charge of coal is laid on, and while the gaseous or more volatile part of the coal is being evolved. The stopping or limiting of the access of air to the coke undergoing combustion prevents the production of carbonic acid gas which ordinarily mingles with and prevents or injures the combustion of those gases which are being evolved from the superincumbent fresh charge of fuel. The furnace is thus converted into a kind of gas retort, and it is only necessary to supply sufficient air for the combustion of the gases arising from the newly-laid-on coals by the heat of the coke. Air may be admitted above the fire at the door, bridges, or sides of the furnace to assist in the combustion of the gases. *Patent completed.*

2657. J. FAIRWEATHER. *Improvements in weaving bags, sacks, and other tubular fabrics.* Dated Nov. 23, 1858.

This refers to bags or sacks for guano, grain, coals, &c., which are mostly made of "jute," or a combination of jute with tow or flax, and frequently with coloured stripes or cotton selvages. The inventor proposes, 1, to employ two sets of warps, and to weave the fabrics double, and either with or without a cord or cords or band of any kind being woven in the cloth at that part of it where the seam usually exists. These cords or bands will give strength and shape to the bag or sack, and they may be formed with loops for hanging or lifting the sack when full; or the cords may be used for tying the mouth of the sack. 2, He proposes to weave one, two, three or more sacks at the same time by weaving a strip or strips of united cloth (that is, weaving the two warps together) between each sack and cutting it after it is woven. *Patent abandoned.*

2658. N. F. BORRHO DE CHODZKO. *A smoke-preventing apparatus.* Dated Nov. 23, 1858.

This relates to an arrangement of coking apparatus to be applied to the upper portion of the front end or mouth of a steam boiler or other furnace of a similar construction, whereby the fresh charge of green fuel is freed from its smoke and combustible gases and coked before being introduced into the body of the furnace. The apparatus consists of a closed chamber placed at the upper part of the front of the furnace, fitted with feeding doors, and supplied with one or more reversing grates upon which the green fuel is deposited. These grates turn upon centres, and are each provided with a hollow shaft which constitutes the turning axis of the grate. To facilitate the turning or reversing of the grates a handle is fitted on to the front end of each hollow axis. The object of making the axis hollow is to enable a supply of air to enter through such axis into the furnace immediately behind the coking compartment, at which point a deflecting plate is fitted for deflecting such air with the smoke and gases from the green fuel down on to the incandescent fuel in the body of the furnace. The charge having been coked, the grates are reversed, whereupon it falls into the dead plate and is pushed forward into the furnace. *Patent abandoned.*

2659. A. V. NEWTON. *Improvements in retorts for generating illuminating gas.* (A communication.) Dated Nov. 23, 1858.

This relates to a novel construction of upright retort, which presents a very large internal heated surface, so arranged as to cause the fluid substance from which the gas is to be generated to be received on a portion of the surface of the retort that is but moderately heated, and to be conveyed gradually from the coolest to the hottest part of the retort, thereby preventing the distillation of the gas-making material into volatile oil, and preventing in a great degree its carbonization on the surface of the retort. The retort is fitted with a helical or screw-like column, having a central tube in which are lateral openings between the threads of the column. A case or cover fits closely to and around the surfaces of these threads, and combines with the column to make a helical passage. The column is supported upon feet which rest on the bottom of the retort, and the case or cover has an opening or openings between it and the bottom of the retort. In the cover of the retort an opening is made and fitted with a lid, which is sealed or luted with fusible alloy, but which can be taken off to admit air to the retort, to burn out any residuary matters which may be deposited on the interior surfaces of the retort in the gas-making process, thereby obviating the necessity of removing the entire head or cover of the retort. *Patent abandoned.*

2660. A. V. NEWTON. *Improved machinery for sweeping floors.* Dated November 23, 1858.

This invention consists in hanging a revolving brush at or near one of its journals in a bridle, and attaching the opposite end of the same bridle at such a point on the case of the machine between the centre of the driving wheel and the other journal of the brush as to make the machine self-adjusting, that is, so that the driving power applied to the wheel shall exceed under all circumstances the friction of the whole brush on the carpet over which it may be traversed, thereby enabling the machine to sweep as lightly or as heavily as may be desired: the peculiarity of this ar-

range being that whatever friction is received by the brush is a little more than equalled by the power applied to the driving wheel. *Patent completed.*

2601. W. WARRE, J. A. JACQUE, and J. A. FANSHAW. *An improved fabric applicable for covering floors and walls and for other analogous purposes.* Dated Nov. 23, 1858.

This consists in the combination of a textile fabric with a compound of india-rubber or gutta-percha, mixed with ground cork and other vegetable substances, such as saw-dust, woody fibre, paper cuttings, or pulp, to which is to be added sulphur, sulphate of lime, sulphate of zinc, or some equivalent compound combining sulphur. *Patent completed.*

2602. R. H. HUGHES. *Improvements in means or apparatus employed when lighting by gas.* Dated November 24, 1858.

This consists, 1. in the prevention of accident from the escape of gas through the hydraulic or such like joints of gas-burners by adapting thereto a whistle, &c., to indicate such escape. 2. In the application of spring or elastic cushions to sliding or hydraulic connections of gas-fittings to check momentum when too rapid motion has been given to the parts in sliding them. 3. In the application of hinge-pieces to the underside of pendant-burners for supporting the glass. 4. In forming globular or other formed glasses, capable for the most part of enclosing the light, with a turned-over edge or projection at the upper part, adapted to receive hooked supports. *Patent completed.*

2603. R. A. BROOMAN. *An improvement in cigar cases.* (A communication.) Dated November 24, 1858.

This consists in connecting two recesses or corrugated plates at the sides only to the inside of a case or pocket made of leather or flexible material and back to back, so that the cigars may lie in the corrugations or recesses in the plates and between them and the case. *Patent completed.*

2604. Sir C. SHAW. *Improvements in the construction of ball and bullet-proof shields or mantlets.* Dated November 24, 1858.

This consists in constructing mantlets or shields of alternate layers of wire netting or gauze, or metal cloth, or metal rods or bars worked and tied together, and hair, leather, cotton waste, tow, or other fibrous material. *Patent abandoned.*

2605. W. E. NEWTON. *Improvements in mills for grinding corn.* (A communication.) Dated November 24, 1858.

Here there are, as usual, two stones, the upper one of which is stationary, and the lower one moveable. The lower stone or runner is surrounded by a case fixed upon a cross-piece, which is attached to the fixed framing. A cast-iron arched piece of framework carries a bearing which supports the spindle of the runner. The fixed stone rests upon the edges of the case of the runner, and three small adjustable pins are adapted thereto, so that the stone may be adjusted with nicety. The upper part of the case is closed, and made air-tight by a band of wood turned and cut to fit. The runner is driven by a band passed round a large pulley on its vertical spindle, and which spindle rests on the end of an adjusting screw, by turning which, by suitable gearing, the vertical adjustment of the runner is effected. The invention also consists in facilitating the grinding and cooling of the meal by driving in air by means of a fan blower between the two surfaces where the grain is under operation. To cool and purify the air it is drawn through a wet sponge suitably placed. *Patent abandoned.*

2606. A. V. NEWTON. *Improved machinery for making bolts and rivets.* (A communication.) Dated November 24, 1858.

Here the dies and headers are combined in a rotary stock, so that they are all accessible for inspection and replacement whether at rest or in motion. The dies are fixed, the one half in clamps hinged to the periphery of the stock, and the other half let into the stock while the headers (one for each pair of dies) work in sockets in the rear of the dies, and parallel with the axis of rotation of the stock. Combined with the stock is a feed-rest and cutter, of such form as to facilitate in the feeding of the rod to form the bolts, and to effect the severance of the rod by the rotation of the stock to form the blanks without expanding the rod at the point severed; and afford support to the point of the bolt or rivet during the process of heading. For releasing the formed bolt or rivet from the dies the hinged clamps are tripped up by a projection on the rear end coming against fixed bowles, and the dies are thus opened. Sliding rods in the dies are then thrust forward by springs, and the formed bolt is ejected from one or other division of the die. The dies are further constructed so that a distinct part forming the shoulder, against which the head of the bolt or rivet will be made, may be easily removed and replaced, and a lip at their outer ends is provided which will not only facilitate the severing of the blank, but leave the end of the formed bolt or rivet slightly pointed. *Patent completed.*

2607. R. H. HESS. *A new manufacture of articles, parts of articles, parts of machinery, surfaces, and ornamental works from talc, and other silicates of magnesia.* Dated November 24, 1858.

The patentee takes certain silicates of magnesia, such as talc, teatite, &c., which he reduces to a state of powder, and presses the material into moulds of the shape of the article to be produced, adding colouring matter when required for black, or various colours, or for staining to imitate marbles, agates, or other substances. *Patent completed.*

2608. C. PETERSON. *Improvements in the manufacture of paper cartridges, and in paper applicable for water-proof purposes.* Dated November 24, 1858.

The inventor introduces a solution of soap into paper pulp, after which he introduces alum in solution, which combines with and decomposes the soap, and forms an insoluble substance which extends throughout the body of the paper or cartridge cases when made, and renders them waterproof. *Patent completed.*

2609. J. S. NIBBS. *Improvements in lighting, heating, and ventilating.* Dated November 24, 1858.

This relates, 1. to a mode of admitting air to the flame of oil or spirit lamps by perforated plates inclined from the perpendicular, and in connection with other perforated plates, whereby the air is divided into small streams, and its force upon the flame considerably checked, at the same time preventing the atmospheric air from coming in immediate contact with the wick of the lamp. 2. To a ventilating top applicable to ship, railway, and other lamps or lanterns, and gas stoves, by which the forcible ingress of air is checked, at the same time allowing a free egress to the vitiated air, &c. *Patent completed.*

2670. J. H. JOHNSON. *Improvements in the employment of electricity as a motive power.* (A communication.) Dated November 24, 1858.

This consists in the use of a number of permanent magnets so disposed that no two similar poles shall face each other. Between these magnets are fitted to play freely a number of soft iron electro-magnets, which will alternately be attracted and repulsed by the permanent magnets by reversing their polarity. The electro-magnets may be made to transmit their motions by any convenient arrangement of mechanism, when a simple electro-magnetic motion will be obtained. There are modifications included. *Patent abandoned.*

2671. C. E. AMOS. *Improved apparatus for raising and supporting ships or vessels while undergoing repair, which apparatus is also applicable for facilitating the passage of ships or vessels over bars, sandbanks, or in shallow waters.* Dated November 25, 1858.

This apparatus is composed of a number of tanks secured together, and being filled with water are sunk under the vessel; then by pumping air into these tanks the water is forced out, the tanks become buoyant and the ship is raised. The invention may be variously modified. *Patent abandoned.*

2672. F. C. CALVERT and C. LOWE. *Improvements in the manufacture of size.* Dated November 25, 1858.

This consists in the application of caustic alkalis for dissolving the gluten or protein matter contained in flour and amylaceous substances used in the manufacture of size. *Patent completed.*

2673. H. EASTWOOD. *Improvements in purifying gas for illuminating purposes.* Dated November 25, 1858.

This consists in forcing gas through or in close contact with either common spirits of wine or vegetable or mineral naphtha, or a combination of these liquids. *Patent abandoned.*

2674. R. BODMER. *Improvements in valves for regulating the supply of steam.* (A communication.) Dated November 25, 1858.

This is chiefly applicable to those valves which are intended to regulate the admission of steam to drying cylinders, where the object is to keep the steam in the drying cylinders as much as possible at a uniform pressure. This is effected by causing the steam in the drying cylinders and that supplied from the boiler to press in opposite directions upon pistons of proportional areas working in cylinders, so that a preponderance of pressure in the drying cylinders will cause the smaller piston to move in one direction, and thereby close the orifice or valve through which the steam is supplied from the boiler, whilst a preponderance in the opposite direction will cause the piston to move accordingly, and to open the said orifice. *Patent completed.*

2675. J. LUIS. *A safeguard against burglars.* (A communication.) Dated November 25, 1858.

The principle on which this invention rests is electro-magnetism. It is by the interruption of the electric current that an alarm of particular mechanism gives a signal—that is to say, at all the places and objects, &c., that are confided to the safeguard of the apparatus, the conductors are interrupted for the time when the places are no longer in a condition of safety, and where the conductors are united in a different manner when it is desired that the places should be inaccessible. By this arrangement, as soon as a hand touches a door or window, or makes any attempt to open it, the electric current is broken instantaneously, and the alarm bell commences ringing. *Patent completed.*

2676. C. F. VASKEBOT. *An improved petticoat and bustle.* (A communication.) Dated November 25, 1858.

This consists in forming a frame in the shape of a fan, the articulations or ribs of which are made of steel bands suitably covered; the upper part of these ribs is bent in the shape of a spring-tong ending with a straight band, likewise covered, the end of which reaches the bottom of the petticoat. The upper part of the tongue is fastened at the waist by a moveable loop tied to the steel band so as to allow it to be lengthened or shortened at will. The open part of the frame is placed in front, and fastens with buttons. The bustle, which forms part of the frame, is fixed underneath the ribs; it is composed of two circles of different sizes kept together at a suitable distance by steel bands. *Patent abandoned.*

2677. J. NUTTALL, G. RIDING, and W. COULTHURST. *Improvement in sizes for sizing cotton, linen, or other warps or yarns for weaving.* Dated November 25, 1858.

This composition is composed of china clay one hundred pounds, or Spanish white one hundred pounds, together with muriate of soda or common salt fifty-six pounds, alum fifty-six pounds, or nitrate of soda six pounds, and farina twenty pounds (if about twenty pounds of flour be also used therewith) or farina forty pounds if flour is not desired to be used. *Patent abandoned.*

2678. F. H. MABERLY. *Improvements in candlesticks.* Dated November 25, 1858.

This invention is not described apart from the drawings. *Patent completed.*

2679. C. PARKER. *Improvements in looms for weaving.* Dated November 25, 1858.

This relates to the taking-up motion, and consists in the use of plain rollers, which may be covered with woollen cloth or other elastic substances operating by a combination of tension and frictional contact upon the woven cloth so

as to take it up uniformly as it is produced by the weaving action. This roller arrangement is disposed in the loom at the front or usual place of the take-up, it being preferred to use a series of three rollers acting in concert. These rollers are carried by their spindles in end bearings in the loom framings, and they are placed one above the other, but so that a line drawn transversely through their centres will form a considerable angle with the vertical line, say an angle of 45 degrees. As the woven cloth leaves the breast beam it passes down beneath the lowest roller of the series and round it, and then between the upper part of that roller and the lower part of the second roller. From this part it passes round or over the top of the intermediate roller, and thence between it and the top roller round which it is wound. The gearing of the take-up motion may be of any convenient kind, the motion from it being communicated to the bottom roller of the series, which roller again is geared by spur pinions with the second roller. The third or top roller runs loose, and is driven simply by frictional contact with the intermediate roller. *Patent completed.*

2680. F. LOOS. *Improvements in gas regulators.* Dated November 25, 1858.

This consists, 1. in placing the valves in gas-regulators in an angular position, so as to maintain an equilibrium. 2. In making the spindle hollow so that it may serve as a lubricator. 3. In making the larger sized regulators in two or more separate parts, the annular groove for the reception of the mercury being attached to the chamber by screws or otherwise. 4. In a lever hinge joint for steadying the disc. 5. In making an outlet for the gas through a spindle attached to the flouting or regulating chamber, which chamber is immersed in an annular cup containing mercury or other suitable fluid. *Patent completed.*

2681. C. MATHER. *An improved steam trap or apparatus for allowing the escape of water and air from pipes, vessels, or chambers heated by steam.* Dated November 25, 1858.

The patentee affixes to the end of a pipe a valve which, when the pipe is heated by steam, is kept closed by a weighted lever carried by a standard mounted on the pipe; but, if any water accumulates in the pipe, the decrease in the temperature contracts the pipe, and causes a short arm on the weighted lever to come against an adjustable stop, whereby the weighted lever is raised and the water allowed to escape; but as soon as steam passes through the pipe, the pipe again expands and moves the short arm of the weighted lever away from the stop, and allows the lever to close the valve. The valve also allows air to escape when steam is first admitted into the pipe, vessels, or chambers after that they have been allowed to cool. This valve also acts as a safety-valve, so that steam may escape if it is at a greater pressure than is desired in the steam-pipes. *Patent completed.*

2682. W. BURTON. *Improvements in preparing colouring matter for dyeing.* Dated November 25, 1858.

The inventor takes a preparation of orchid, which he dries and reduces to powder, and then boils or heats with naphtha: afterwards he separates it by filtration, and dries it. When this substance is used in dyeing, oxalic or other acid is used with it; or, in place of this process, the preparation of orchid is treated with alcohol, ether, or chloroform, which dissolves the colouring matter, and the dye-bath is prepared from the extract thus obtained. *Patent abandoned.*

2683. J. LUIS. *A new sort of drawers or trousers for ladies or children.* (A communication.) Dated November 26, 1858.

The patentee claims the application of springs or any other arrangement for retaining or giving form to the drawers or trousers. *Patent completed.*

2684. J. HARRISON. *Improvements in rollers applicable to sizing, dressing, calendaring, and squeezing machines.* Dated November 26, 1858.

This consists in making these rollers of slate, marble, or stone. *Patent abandoned.*

2685. E. DIXON and F. FISHER. *An improvement in the manufacture of welded iron tubes.* Dated November 26, 1858.

This consists in the use of two draw-benches. The inventors place a second draw-bench near, and by preference parallel to the one situated opposite to the mouth of the furnace. After the partially-made tube has been drawn through one draw-bench, so as to effect the welding of the joint of the said tube, they transfer it to the second draw-bench, by the operation of which the final drawing and completion of the tube is effected. *Patent completed.*

2686. A. BOWIE. *Improvements in governors for marine engines.* Dated November 26, 1858.

The improved apparatus, which is more particularly applicable to screw steamers, consists, under one modification, of a weighted lever, combined with a valve on the pipe conveying steam to the engines. The weighted lever is hung so that its tendency to hang plumb, or with its centre of gravity in its lowest attainable position, shall cause the valve to close, to a greater or less extent, when the vessel becomes inclined longitudinally with her stem elevated; and this action, by reducing or cutting off the supply of steam, will have the effect of preventing the engines from running away. It is preferred to make the valve of the equilibrium class, or so as to be actuated with as little force as possible, and the weighted lever may be jointed to enable the weight to swing freely in a transverse direction without acting on the valve. The invention is susceptible of being applied to vessels propelled by paddle-wheels. *Patent abandoned.*

2687. M. MEYERS. *Improvements in parasols.* Dated November 26, 1858.

The inventor covers the ordinary parasol frame with a cover of two pieces or two outside covers of different dimensions: the same to be lined with cotton, linen, alpaca, &c. The rims of the lining and covers are formed into falls or flounces, having their edges pinked or cut into fancy patterns. The parasol is also furnished with an ornamental bow. *Patent completed.*

2688. M. A. F. MENNONS. *An improved manufacture of leather.* (A communication.) Dated Nov. 26, 1858.

The object here is the production of a semi-transparent leather susceptible of many of the applications of ivory, bone, whalebone, and analogous materials. The raw hides are soaked in a solution of lime to remove the hair, &c., and are afterwards submitted to intense pressure. *Patent abandoned.*

2689. G. RICHARDSON. *Improvements in machinery or apparatus for pressing bales of goods.* (A communication.) Dated Nov. 26, 1858.

Here it is proposed to arrange any required number of presses below the roadway of a railway siding. These presses consist of rams or pistons working in chambers of stone or wood and fitted each with a piston rod, the top of which carries an anti-friction roller, and projects, say feet above the level of the rails in the centre of the roadway. The chambers are fitted with side doors, and suitable fastenings for the facility of introducing the goods and removing the compressed bales, and the top and bottom pressing surfaces are grooved to admit of bands being placed around the bales. The pistons of the presses are forced down by the travelling over them and along the line of a loaded truck having a bar or beam attached beneath it longitudinally in an inclined position, the highest end going first. As the truck passes along, the inclined bar passes over the several piston rods and depresses them. The pistons when compressed are held down by self-acting catches, which, when released by hand, allow the pistons to rise again by the action of counter-weights. *Patent abandoned.*

2690. T. B. HUBBELL and G. J. ROLLASON. *Improved apparatus for brightening and polishing metal surfaces.* Dated November 26, 1858.

This consists in forming polishing apparatuses by uniting several discs of leather, felt, &c., by sewing them together by one or more rows of stitches, the outer row being some distance from the periphery of the discs, so as to leave the outer edges of the discs open that they may hold between them the polishing powder. *Patent abandoned.*

2691. J. B. BOOTH. *Improvements in machinery or apparatus for preparing, spinning, doubling, and winding cotton and other fibrous materials.* Dated Nov. 26, 1858. This invention is not described apart from the drawings. *Patent completed.*

2692. W. RICHARDS. *Improvements in the construction of gas-meters.* Dated November 26, 1858.

This consists in constructing the measuring wheel or drum with chambers having a diminished capacity near the axle. The patentee attains this end by forming the wheel with sides inclining inwards towards the axle instead of making the sides parallel to each other; thus the great variation in the measuring capacity of the chambers at present experienced by the alteration of water line will be reduced to an inconsiderable amount. When using this construction of drum-wheel the part called the hollow cover can be made flat or concave (the conical space at the inlet side of the wheel allowing sufficient space for the insertion of the spout) and thus a broader drum than heretofore can be mounted in a given size of case. In addition to contracting the measuring chambers laterally near the axle of the drum he proposes to place the cross partitions which divide the wheel or drum into chambers at a much greater angle to the axis than heretofore, in order that the resistance to the water may be as uniform as possible, and he so arranges the inlet and outlet passages of each measuring chamber that the bulk of water entering by the inlet to displace the gas shall be as nearly as possible equal to that of gas replacing the water in the outlet. It further proposes to place a plumb valve at the back of the meter (the opposite side to that at which the float is situated), which will serve to prevent surreptitious abstraction of gas by the meter being tilted forward. *Patent completed.*

2693. P. GRIFFITHS and J. BRENNAND. *Improvements in lubricators for introducing lubricating matter into steam cylinders and other chambers or parts under pressure.* Dated November 26, 1858.

This invention is not described apart from the drawings. *Patent completed.*

2694. J. SEBAST. *Improvements in the manufacture and strengthening of paper.* Dated November 27, 1858.

This consists in combining yarn or threads with paper pulp while in the form of a sheet as it is formed in the paper-making machine for adding strength to the paper. In course paper wire is applied. *Patent abandoned.*

2695. J. TANGYE. *An improvement in hydraulic presses.* Dated November 27, 1858.

This consists in making the cistern in the base of the press, the said base being hollow. The invention is not described apart from the drawings. *Patent completed.*

2696. J. RAMSBOTTOM. *Improvements in machinery or apparatus applicable to water metres, and to indicating and regulating the flow and pressure of fluids generally, and in obtaining motive power from the same.* Dated Nov. 27, 1858.

This consists, 1, in constructing the valve and water ways so that whether the valve be flat, or plug shaped, relatively to each other the supply and exit ways shall be open whilst the valve shall traverse over one-third more space than was accomplished in the former mode of construction. 2, in constructing the valve in a slightly different manner, and in using it inverted as a seating, upon which a boss shall rotate containing a cavity of suitable size into which the fluid shall pass during a certain portion of the revolution, and out of which it shall escape for use during another portion of the revolution. The boss must be suitably ground upon the seating, and carry a wheel worked by a worm or pinion situated at right angles, such worm or pinion to be actuated by any motion, and the arrangement thus made available for lubrication. 3, in an improved arrangement for actuating valves by the expansive force of a series of two or more metals which are acted upon differently by the same temperature. *Patent completed.*

2697. G. COLLIER. *Improvements in means or apparatus employed in weaving.* Dated November 27, 1858.

The object here is the obtaining of an elastic beat up to

the batten or lay, capable of being varied in power or degree. The links or arms which usually connect the lay or batten to the crank or other means employed to govern the extent of motion to the batten, in this case connect the cranks, or equivalent to a separate arm or arms rising from or near to the axis of the lay swords, so that the batten or lay may, except when otherwise controlled, be capable of considerable vibration, and the connection of the batten or lay with the separate arm or arms, so as to cause them to move together for the time required, is effected by a lever or levers with catch or catches operated by cams or tappets in such manner that the batten and separate arm or arms moved together for a time, and then by the batten being released, an elastic beat is obtained, varying in power or degree with the time when, in the rotation of the crank shaft, the batten becoming released. The separate arm or arms may be connected with or without hinge joint, and a spring or springs may be employed to aid the motion of the batten in beating up. Also the invention relates to effecting the motion to beat up by a spring or springs, and in giving motion to the batten or lay in the direction from the cloth by means of cams or tappets acting upon links or connections from the batten or lay, the links or connections being attached to the batten or lay at or near where the links are usually connected when using the ordinary crank motion. The invention further relates to preventing the fabric from creasing as it is taken by the work roller, by stretching the fabric breadthwise by means of rollers with roughened surfaces, or with the peripheries provided with teeth. *Patent abandoned.*

2698. R. ALEXANDER. *Improvements in treating, preparing, and bleaching textile fabrics and other materials.* Dated November 27, 1858.

Here the fabrics are passed in an open sheet form slowly through steam chests, instead of being subjected to the boiling process. *Patent completed.*

2699. F. C. KIMMEAR and D. POSENER. *Improvements in the means of preserving life and property in navigation.* Dated November 27, 1858.

This consists in the attachment of inflated air-tight tubes or bags to the internal or external sides of ships, &c. The material preferred for making the tubes or bags is that known as double texture or Mackintosh cloth. *Patent abandoned.*

2700. H. L. PATTERSON. *Improvements in utilising the heat of slags of iron and other works.* Dated November 27, 1858.

This consists in employing by the aid of suitable apparatus the waste heat of slags of iron in the heating of arciform and other fluids. The apparatus may be varied, but it is preferred that the hot slags should be caused to move through suitable channels, whilst the air or other fluid is contained in other contiguous channels, and by preference caused to move in an opposite direction to that in which the slags move. *Patent completed.*

2701. C. BURRELL. *Improvements in traction engines and carriages.* Dated November 27, 1858.

In constructing the wheels which run on the portable railways trough or double angle iron is used, so that there are two rows of iron spokes to each wheel, the outer ends of which are fixed to the trough iron or double angle iron ring, and there are openings or spaces through the trough or double angle iron for the passage between the two rows of spokes of the A formed bars or projections which connect the shoes constituting the portable railway with the wheel, the shoes being each formed with two parallel rails on their upper surfaces on which the tyre of the wheel runs, the A formed bar or projection being fixed to the shoe between such parallel rails and the guide irons, for such projections are fixed to the trough or double angle iron so as to come on each side of the projections. In gearing the main or driving shaft with the driving wheels pinions are affixed (one at each end of the driving shaft) which when in action gear into the cog wheels on the driving wheels of the carriage, and the boiler and engines are so carried by the axle of the driving wheels that they may be raised or lowered thereon by screws and levers, by which means both or either of the pinions on the main driving shaft may be put in gear with the cog wheels of the driving wheels of the carriage, or both the pinions may be out of gear with these cog wheels according as the end of the boiler is raised or lowered in respect to the main or driving shaft. *Patent completed.*

2702. G. B. SANDER. *Improvements in jugs.* Dated November 27, 1858.

This consists in applying to the covers of jugs a moveable stop to prevent the cover rising further than is requisite to allow the liquid to be poured out, but which can be turned out of the way to allow of the cover being fully opened to fill or clean the jug. *Patent completed.*

2703. W. TILLIE. *An improvement in the manufacture of shirts and shirt fronts.* Dated November 27, 1858.

This consists in printing linen, &c., so that material for the whole front part of a shirt, together with wristbands and collars may be furnished by one breadth of cloth, the front being without folds, but printed with any suitable pattern, and the collar and wristbands being likewise ornamented. *Patent abandoned.*

2704. S. DIGGLE. *Improvements in pattern chains or other such apparatus used in weaving.* Dated Nov. 27, 1858.

This relates to the pattern chains or other such apparatus used for shifting the position of the shuttles in what are commonly called "rising box looms," and also to other pattern chains or similar apparatus used in fancy weaving for shedding the warp, &c. The invention is not described apart from the drawings. *Patent completed.*

2705. H. GERNER. *Improvements in the mode of and apparatus for manufacturing gas for illumination and heating.* Dated November 27, 1858.

The inventor mounts by preference a vertical retort in a furnace and fits the retort with one or more pipes for conducting thereto the material to be converted into gas. When making illuminating gas he uses a retort fitted with a pipe for supplying the liquid hydro-carbon to be converted into rich carburetted hydrogen gas, and also a second

pipe for supplying water which is intended to yield pure hydrogen. These pipes each terminate in a pierced coil, and the coils are surmounted with scrap iron, &c., which fills the retort about two-thirds full. Pressure being put upon the fluids by the elevation of the water and hydro-carbon tanks a continuous supply is afforded to the retort. These fluids flowing down their respective pipes and circulating round the coil find an exit through the perforations in the coils in the form of fine streams of vapour, which on coming in contact with the red hot scrap iron in the retort become converted into gas. The hydrogen gas obtained by the separation of the water into its elements is generated at the hottest part of the retort and travelling upwards it meets with the hydro-carbon gas, and mingling therewith takes up and chemically combines with the excess of carbon that would otherwise be deposited in the retort. The combined gases then pass off by a syphon pipe into a purifying vessel where they are cooled and made fit for burning. When manufacturing gas for heating purposes he dispenses with the use of the liquid hydro-carbon and the apparatus employed in supplying it to the retort and obtains the gas solely by the decomposition of water into its elements. *Patent abandoned.*

2706. L. A. POSSOZ. *Manufacturing alkalies, and obtaining simultaneously other chemical products.* Dated November 29, 1858.

This consists principally in certain processes in which soda or potash is employed in the state of chlorides, sulphates, silicates, crude salts or other alkaline combinations. The salts being brought into the state of caustic potash or soda, the alkali is heated with organic substances asoted or not, and if asoted he obtains from them ammonia, but in any case he obtains oxalates, acetates, carbonates of potash or soda, which has not been hitherto accomplished. In this manufacture he does not use again the acetates and carbonates first used by submitting them each time to a new process of caustication to render them useful again, but he takes each time the caustic alkali which he wants from the low priced salts, and obtains by his process acetates and carbonates either by purifying them ready for sale in a commercial form, or using them to produce cyanures or other chemical products. *Patent completed.*

2707. G. OATES. *Improvements in the manufacture of scissors.* (A communication.) Dated November 29, 1858.

This relates to the introduction of dies in the process of scissors making by which a uniform configuration of the sides or bows may be obtained, and elaborate ornamentation impressed upon them at a relatively small cost. The invention is not described apart from the drawings. *Patent completed.*

2708. M. STARNBUCK. *A static pressure engine.* Dated November 29, 1858.

This consists in the application of a static pressure to produce a continuous movement from which the static pressure (minus the friction of the engine) can be continually given off for moving any machinery to which the engine may be applied. *Patent abandoned.*

2709. F. S. PERRARE-MICHAEL. *Improvements in the manufacture of bridles (without bits and without curb-chains) for riding, driving, or otherwise conducting horses.* Dated November 29, 1858.

This bridle is constructed as follows:—The head stall is the same as those now in use, except the part called the nose-band, which has on the inside a small piece of steel, &c.; it is placed in the centre so as to press on the nose of the animal, the pressure being obtained by the connection it has with the apparatus intended to replace the bit, and by which the animal is guided. This apparatus consists of two pieces of steel, &c., connected together by a bar or bars of the same metal; one of these bars passes over the animal's nose, and acts as a lever lifting up and down; the other bar goes into the mouth, but does not in any way affect or press on the animal's mouth; the bar or lever passing over the nose has two rings to which are attached the reins, and it is by these reins that the lever is lifted up or down, and consequently pressed more or less on the animal's nose. The apparatus is fixed to the head stall by buckles, and at each side the branch of the apparatus enters into a long loop on either side of the head stall. *Patent abandoned.*

2710. G. COLLIER and W. NORRIS. *Improvements in means or apparatus for the manufacture of spokes for carriage wheels, which improvements are also applicable to the cutting of wood for other purposes.* Dated November 29, 1858.

Here the wood to be cut is held endwise as in a lathe, and so that rotary motion may be given to it, whilst it is acted upon by two rotary and traversing cutters. One of these cutters in its rotation during its traverse simply acts to reduce the outer surface of the wood to a cylindrical character. The other cutter is also capable of a motion in a direction to or from the wood to be cut, and a projection or follower from the sliding table supporting it is constantly borne towards a model spoke or other form being copied, and which is caused to rotate simultaneously with the wood to be cut, by which the article cut will by this second cutter be cut to the figure of the model. In order to give steadiness to the wood being cut especially towards the centre of its length, it passes through a fixed trace or support of a form suited to embrace the wood just after being operated upon by the first cutter, and before being acted upon by the second. The cutters employed for cutting spokes and such like articles are of a disc form with cutting edges formed across the periphery in an angular direction, and such cutting surface of each cutter is partly cylindrical and partly curved to a smaller diameter, so as to enable them progressively to cut from the outer surface to the depth desired, and the face of the cutter in the direction of its cutting is all round it, near its cutting edge, recessed or dialed, so as to admit of sharpness at those parts. *Patent completed.*

2711. W. E. NEWTON. *Improved expansion or cut-off gear for steam-engines.* (A communication.) Dated November 29, 1858.

This consists in certain combinations of vibrating arms, vibrating links, rods, and lifters, whereby the "cut off"

ships of the line afloat, 37 frigates, and 140 corvettes, sloops, and gun vessels—50 sail-of-the-line, independent of the block-ships.

But we are not, according to Lord Clarence Paget, to suppose that our naval strength is limited to these ships and vessels. From a return moved for by the hon. member for Penryn a few days ago it appeared that the number of steamers over 1,000 tons was 159, that the total number of registered steamers was 1,854, and that there were 231 steam vessels in the merchant navy, any of which might be armed with Armstrong's guns, and which would prove a valuable addition to the defences of the country. There was another source from which the navy of this country might be very largely increased at any moment—viz, the ships from the merchant yards. He produced a return which could not but be interesting to the House. There were 10,000 shipwrights in Great Britain in addition to those employed in the Royal dockyards. Now, the old shipwright maxim was that 1,000 shipwrights would build eight ships of 1,000 tons in 12 months; consequently 10,000 men would build 80 corvettes of 1,000 tons each in 12 months, or between six and seven corvettes per month. If we were pressed for ships there could be no doubt that, giving the shipwrights a little while, say four months, to start with, they would be able to build half-a-dozen very large corvettes per month in the merchant yards, and the steam machinery that could be produced would be in proportion. His (Lord Paget's) object was to show what the public were, he thought, anxious to know—whether this country was really in a state that befitted its honour and dignity. He believed that the navy was now in that state.

The next portion of Lord Paget's speech which invites our notice is that relating to the employment of extra shipwrights in our dockyards during the ensuing year. Besides the ordinary wages of shipwrights there was an extraordinary charge, called by him the "reconstruction" charge. There was also a large sum in the supplemental estimates under the head of wages to artificers. He explained the history of this transaction as follows:—Up to March last the men in the dockyards were working in the usual way on day pay. But in March the late Government thought fit to commence a system of task and job work, and also to enter a considerable number of additional artificers. There were 1,484 shipwrights entered in addition to a corresponding number of other workmen. In April, again, the late First Lord of the Admiralty considered it important, probably from circumstances connected with foreign affairs, to make additional exertions; and then commenced a system of over-hours, that was to say, besides the institution of task and job work, men were allowed to work over hours, and so the dockyards went on until May, when there came a large increase of no less than 1,350 shipwrights and other artificers and labourers; making a total of 17,690 workmen now employed in the dockyards against 14,128 employed in the month of March. This was a very great increase, and he (Lord Paget) believed that the increase was absolutely necessary. He thought that Sir John Pakington deserved the gratitude of the country for having taken this matter in hand, and for having come to the decision of raising the amount of workmen in the dockyards with the least possible delay. The present Government, on coming into office, looked very carefully over this vote, and they sent for the Surveyor of the Navy, Sir B. Walker, and asked very particularly for what period this additional expense would provide pay for the additional men; and Sir B. Walker stated that it would only pay the men

up to the month of October. It would be very unwise that that body of men should be discharged, when the short days of winter were coming on, when over the country work was scarce, and, moreover, when there would still remain in the dockyards a vast amount of work to be done; and therefore the Government had resolved to keep them on till the end of the financial year, and to ask for an additional sum of £100,000 on that account. This was a sufficient answer to the statements which had been made, that the present Government intended to cut down the expenditure in the dockyards, and to cease the efforts which were being made to put our navy upon a proper footing.

The new Secretary's speech was most meagre in reference to ships building by contract, and to new works, improvements, &c. The substance of it was, "The sum taken in the original estimates for ships building by contract was £252,000, which was the first instalment for two iron-cased frigates, one of which would be launched on the 18th of April next—the total cost of which he was not then in a position to state. In addition to this sum there was in the supplemental estimates a vote for eighteen gun vessels of a very superior class, which were to be built by contract. With regard to vote No. 11 for new works, improvements, and repairs, the new Board of Admiralty, having had no time to visit the different dockyards, had formed no independent judgment. Each year we built larger ships, and consequently had to enlarge our docks; and he supposed we should go on in the same way until there came a change, and ships were reduced in size." From this we conclude that a second "steam ram"—as newspaper writers are so fond of calling the vessel now building on the Thames—is not to be undertaken this year. No further attempt is, it appears, to be made with the view of resisting those formidable "*frégates blindées*" which the French are building with all despatch.

DECIMAL COINAGE.

In pursuing further the question of a decimal coinage, let it not be supposed that we are wedded to the idea that its introduction is an absolute necessity, because such is not the case. It has been shown in these columns that there exists an urgent need of a mechanical reform in regard to the silver and copper currencies of the kingdom, and the consideration naturally arises, "Is it not prudent in conjunction with that mechanical reform, which *must* be effected, to reform altogether the scale upon which those currencies are based?" If it can be demonstrated by Lord Overstone, or Lord Anybody, that in making choice of a new metallic currency, and dismissing altogether prejudice, old associations, and habit from interference with the subject, it would be advisable to copy the present antiquated duodecimal system, and perpetuate it—if we say this can be incontestably demonstrated, then are we duodecimalists too! Hitherto, this assuredly has not been done, and, in spite of the final report of the last Decimal Coinage Commissioners, there are in both Houses of Parliament, and in the monetary and commercial sections of the community, many who dispute altogether the superiority of the existing system to that of the pound and mil, as proposed by Sir John Wrottesley in 1824, and supported by a long train of scientific men since. It is not in the spirit of controversy that the matter is here introduced; there has been too much controversy already. Decimal systems—for there have been several placed before the public—were discussed, written about, and lectured upon with a species of literary and mutual *pounding* and *milling* which blinded

the disputants to facts, and made them the excited advocates of fanciful theories, rather than philosophical students in search of the truth. Calmly, and apart from any pugilistic thoughts, would we touch the decimal question, and having last week given something like an historical *résumé* of the agitation in favour of it, now proceed to remark upon the report which, for the moment, seems to have extinguished that agitation.

In the first place, as it appears to us, the Commission was far too limited as regards the number of its members. Three gentlemen only, however talented, were not competent to deal with the weighty business intrusted to them, and the retirement of Lord Montague before any but the preliminary report was agreed upon, made the court still more inadequate to the task. It is not likely that any disparagement of so eminent a man as Lord Overstone will find utterance here. Noble by reason of his vast ability as by his rank, his lordship's fame is beyond detracting. We cannot regard Lord Overstone's report nevertheless—for virtually the final report of the Commission is *his* alone—we cannot regard his report as decisive of the fate of decimalization in England. Unlike the *Saturday Review*, we consider the question of pound and mil still as an open one, and shall endeavour, by making some perforations in his lordship's report, to let in a little more light on the vexed subject.

Perhaps there is no one man who has so thoroughly considered the question of decimal coinage as Sir John Bowring, who, we rejoice to see, has returned home after the successful accomplishment of one of the most arduous tasks which could fall to the lot of a statesman, and who we trust will not fail to meet a due reward at the hands of his countrymen. Sir John Bowring, it will be remembered, published in 1854 a work on the decimal coinage, and the amount of laborious research and of scientific acumen which his book displayed places its author almost at the head of the supporters of the decimal system. Back to the very infancy of civilization in the nations of antiquity does Sir John look for evidence of the superiority of the decimal scale of notation, whilst the Scriptures themselves are put under contribution in support of his arguments. With this ancient data we, however, are not intending to load our columns. It will be enough for us to prove that, in the present position of commercial affairs in England, the introduction of a decimal system of coins would be a boon.

We have seen that the great arguments of most of those who are opposed to the reform or remodelling of the coinage upon the decimal system, are the amount of confusion which the act of transition would create, and the vexation and loss which would fall upon the small shop-keeping classes. In our opinion, these evils would be found more imaginary by far than real. Those amongst us who have travelled on the Continent are quite aware of the facility with which one falls into the method of calculating the cost of everything in the monies of the particular countries through which he passes. Even our friends the "navvies," that useful body of men, to whom not only England but the world is largely indebted—the "navvies" have been found to possess, after one or two lessons, the 'cuteness necessary for preventing their being victimised by the natives of those remote districts of Europe where they have been engaged in their useful occupations, and where decimal coinages existed. Engineers and contractors have furnished abundant evidence on this head.

In the "draft report" of Lord Overstone, facts of this kind—which to our thinking are the

strongest proofs of the absence of difficulty in making the change at home—facts of this kind, we say, are lightly brushed aside because the unit, or starting point, of those coinages is not as it would in the pound and mil scheme be, the pound sterling. There is, no doubt, some little ground for thus getting rid of the mass of evidence which travellers of every grade will be willing to furnish in favour of a decimal coinage, but indeed to us it seems that his lordship was driven to extremities when he availed himself of that ground. Without coming to the penny scheme, which, though having some advantages over the pound and mil scheme, is yet admitted to be inferior to it in many other respects, let us deal at once with the latter. It was stated in the report of the Select Committee of the House of Commons, dated August, 1853, that that committee was “unanimous in recommending the pound sterling as the unit. Considering,” that report went on to state—“considering that the pound is the present standard, and therefore associated with all our ideas of money value, and that it is the basis upon which all our exchange transactions with the whole world rests, it appears to the committee that any alteration of it would lead to complications and embarrassments in our commercial dealings; in addition to which it fortunately happens that its retention would afford the means of introducing the decimal system with the minimum of change. Its tenth part already exists in the shape of the florin, while an alteration of four per cent. in the value of the farthing will serve to convert that coin into the lowest step of the decimal scale which it is necessary to represent by an actual coin, namely, the thousandth part of a pound. To this lowest denomination the committee purpose, in order to mark its relation to the unit of value, to give the name of *mil*. The addition of a coin to be called a cent, of the value of ten mils, and equal to the hundredth part of a pound, would serve to complete the list of coins necessary to represent the monies of amount, which would accordingly be pounds, florins, cents, and mils.”

Such was the very distinct and unmistakable definition of the pound and mil scheme of 1853, and such is a clear exposition of that scheme as it stands now, and was dealt with by Lord Overstone—we beg his lordship's pardon—by the Commission which has recently delivered itself of its final report.

We have not time nor space to follow Lord Overstone's wanderings through France, Sardinia, Belgium, the Netherlands, Switzerland, Russia, and America, in his search for condemnatory evidence of decimal systems in general, and of the proposed pound and mil system in particular. It is quite certain that foreigners generally prefer the particular decimal plans which may be employed in their own countries; and there has unquestionably been much skill employed in framing many of them to suit the peculiarities of the peoples of those countries. It is admitted by his lordship that men of science throughout England are almost universal in their faith in the practicability of a decimal coinage, as also of its great value and simplicity as compared with the existing system. Among these scientific men, indeed, may be named the late, and the present master of the Mint, Sir John Herschel and Dr. Graham, Professor de Morgan, Sir William Hamilton, and many others. The scholastic profession, probably from their intimate acquaintanceship with decimal notation, are strong advocates of a decimal coinage. The coins themselves, they say, would teach the people generally how to avail

themselves of decimal calculation, whilst the latter would save them time, which is money!

There are many other points in regard to this important subject which ought to be touched upon; but feeling assured that the present Government will not rest satisfied with the able but one-sided report of the last Commission, but at once appoint another, of which Sir John Bowring shall be a member, we reserve them for consideration at some future day. Our own decided conviction is that the further introduction of the decimal system has been too long delayed, and that the late Commission has raised about it a cloud of mystery and doubt which one year's practical experience of the pound and mil system would cause to vanish like the mists on the mountain tops on the appearance of the morning sun.

So far from sweeping away the florin, of which Lord Overstone, with a good old-fashioned prejudice in favour of the half-crown, professes himself tired, we hope to see the day when the supplementary coins alluded to shall issue from the Mint, and prove themselves the best arguers in favour of the decimal system.

THE LOCOMOTIVE: ITS PLACE IN HISTORY.

In Mr. Buckle's “History of Civilisation,” the following bold opinion is expressed: That the locomotive steam-engine has done more to unite mankind than all that philosophers, poets, and prophets have taught from the beginning of the world; and this is so emblematic both of the worth and of the defects of this noble book, that we give it in these pages as a sort of window-peep into the whole.

This sentiment well expresses the writer's healthy, brave appreciation of things material and secular. No doubt, in the theory of life we have been educated in, there has been a most unholy divorce of the material life of man from his mental life. In nature, in idea, these two are one; and to make them one in universal fact is the great task of mankind. The street, the shop, or the cloth-mill is as holy a place as the church, if intelligence, heartiness, and conscience be there. The steam-engine, looked at as the product of mind, is as holy as a prayer-book; and when employed by mind for noble ends, performs a true divine service. In short, bring the whole man into any material act, interpenetrate it with energy, intellect, heart, conscience, and the act is no longer material, but as divine as the breath of prayer.

It is said of Dr. Arnold, that when he first saw the railway-train shoot by, he exclaimed, “That's the death-blow to feudalism.” In the same spirit is the locomotive the favourite of Mr. Buckle. He is the firmest, most entire, and most pitiless foe of all artificial and false restrictions. Undo every fetter you have laid upon man, is the voice of his book from beginning to end of it. The inmost life of it is a protest against all false restraints. Thus Adam Smith, the father of our modern free trade, in writing the “Wealth of Nations,” is extravagantly said to have given us, considering all its results, the most important book that ever was written. And just as inveterate is Mr. Buckle against false social as false fiscal restrictions. So democratic is he, it really seems a pure misfortune in his eyes to be born with a title and a name.

But, returning to our point, will the fondest believer in machinery thus exalt the steam-engine above the philosophies and poetries of the world? Mr. Buckle has shown, towards the close of his book, how the French, wholly ignorant of us English people during the reign of Louis XIV., after his death suddenly became acquainted with and enamoured of our manners

and institutions, our independence of speech and thought; and that this, working and fermenting in the best French minds of the 18th century, was, more than anything else, the cause of the great Revolution. What had the railway and steamboat to do with this? Or, to take an instance nearer home, has not the steam-engine been very busy recently in bringing French and Austrians together, and was it then “the bond of unity?” We would not be profane enough to ridicule a sacred fact. The steam-engine is a divine element in the civilization of the world. But the writings of Locke and Shakspeare are diviner than it; and only in the hands of a people transformed by thoughts like theirs can the steam-engine play its true part. This is the one great defect of this “History of Civilization,” that it overrates what is material and external. It makes the character of whole nations depend upon food and climate. It sets up a doctrine of averages drawn from statistics, as throwing more light on the moral nature of man than all the accumulated experiences of former ages. It traces to external accident what the inspirations of individuals and races have achieved. It calls Cromwell's war a secular war; and Bacon's and Shakspeare's books, secular books. It makes the superiority of Protestantism over Catholicism to consist purely of a superior common-sense and wider tolerance of difference of opinion. It exalts tolerance above conviction. It exalts common-sense above reason and imagination; “useful knowledges” above metaphysics and poetry. And this, too, with a strange inconsistency; for the main figures of this book are men of a metaphysical bent: Montaigne, Descartes, Bichat, Locke, and Newton. No doubt man is a unity; and 'tis foolish to pit one faculty and possession against another. But 'tis equally true that there are grades and stairs of existence. There are things for the senses; things for the logical or ratiocinative power in us; and there are things for belief, wonder, and love. Adam Smith gave us much; Watt still more; but Shakspeare, Homer, and Plato far more than they. Community of trade, community of intercourse, community of knowledge and opinion are unspeakably good; but community of perception, conviction, belief, good-will, far better. These come from within, not from without; are in greater plentitude in some races and ages than in others; in some individuals than in others. They are checked or furthered by innumerable conditions and circumstances, but created or killed by none of these. They do not quite depend upon “climate and food.” They can come upon an Egyptian, or an Arabian, eating dates, surely, or upon a Hindoo that subsists on rice, as upon a European eating bread in his temperate climate. Their rise and decline are not calculable by any doctrine of averages. They come as the summer lightnings and the summer breezes, when and where we cannot foretell.

THE ROYAL AGRICULTURAL BENEVOLENT COLLEGE.

THERE is no greater characteristic of the present age than the rapidity with which long-rooted prejudices have been removed, and their places taken by well-grounded and enlightened views. And in no one especial direction is this more remarkable than amongst the agricultural community of Great Britain. It is within the recollection of even ourselves that the farmers, as a body, persistently opposed every innovation against prescribed rules in reference to their soil—rules that were told off upon their fingers, and were revered and followed only because their fathers revered and followed their fathers before them. When it was first made apparent that the plough could be rendered less unwieldy, and

do as much with two or even one as had before taken six horses to manage, the sharp edge of improved mechanical appliances entered not only the earth, but the minds of the most important members of the landed proprietors also. Prejudice, driven from the centre of the citadel, took refuge in the outposts, and amongst the working men reigned triumphantly for a time. The destruction of machinery by the illiterate and ill-advised labourers perhaps hastened its development, inasmuch as opposition is a great element in producing the essentials of perseverance in the English character. Chemistry followed close upon mechanics, and the wonders worked in consort with agriculture are now before the world. It is not, then, a matter of surprise to find the *trio in juncta* linked and bound together as with one mind, and zealously engaged in consecrating so great a victory.

"The Royal Agricultural Benevolent College for the Relief of Decayed Farmers, their Widows and Orphans," is the embodiment of a co-operative thankfulness for a grand and continuous social progress. The thought, we believe, has emanated from Alderman Mechi, who, it would seem, has by the application of a simple, soul-stirring appeal from Tiptree, practically effected the humane object of his advocacy. Already the first men in literature and the arts, whether in the ranks of wealth or genius, have given in their adhesion to the proposal; and so great has been the instant success attendant upon the promulgation of the scheme that, strange to say, for once, it has left the important labours of the journalist far in arrears. The pen has to record what *has* been done, not that which it is desired to do.

We cannot do better than reprint a few extracts from the addresses of Alderman Mechi upon this subject, and we do it not as a work of supererogation but as placing on record the fact that, with energy and tact, great good may be effected, and that as the field of philanthropy is by no means over-cropped, others may profit by this example of the Christian farmer, who has left the gate open for those who would glean, and showed the way to yet further tillage for the production and fruition of good works.

"If we reflect for one moment," says Mr. Mechi, "wherein can we discover a reason why the industrious farmer should be specially screened from the frowns of fortune, or those vicissitudes which are the painful lot of every other class? Why should he expect to be exempt from that stern misfortune and bitter poverty which we see so frequently too painfully illustrated in every other department of daily life? None can say that his risks are less frequent, or his chances of success more certain. Why, then, should he in his suffering and his tribulation be shut out and excluded from the enjoyment of that support and sympathy which are diffused so profusely throughout the length and breadth of the land, for the benefit and solace of every suffering class but his own? Let us remove this reproach. Let us assume that place in so noble and charitable a list which the influence and the dignity of agriculture demand, and I am assured the bare mention of such a project for the amelioration and relief of those who, while suffering, complain not, will speedily realize such a happy and much-needed consummation. Towards the fulfilment of such an object, I have received promises of hearty and zealous support from some of the leading agriculturists and implement manufacturers in the kingdom, who most cordially sympathize with the suggestion. One farthing per acre, on the 48,000,000 acres farmed in this country, would produce £50,000, or, if one-fourth only gave one penny

per acre the same amount would be produced. "It is a cause in which the humblest may do good, the 50 pennies from the 50-acre farmer will, in its proportion, do as much real good as the contribution from the 10,000-acre holding; do not, therefore, permit a false delicacy to crush a good intention, but give it existence in a cause that will bear you tenfold interest hereafter."

THE CASE OF HENRY CORT, AND HIS INVENTIONS IN THE MANUFACTURE OF BRITISH IRON.

BY
THOMAS WEBSTER, M.A., F.R.S., &c., Barrister-at-Law.
No. V.

HENRY CORT, the author of these inventions and of that system which has been described as constituting the third epoch in the history of the British iron manufacture, was born in 1740; his father was a builder at Lancaster.

About the year 1765, Henry Cort had established himself as a navy agent in Surrey-street, Strand, and in 1768 married Elizabeth Heysham, the daughter of a solicitor in Staffordshire; and steward of the Duke of Portland. The issue of that marriage was as follows:—

Henry Bell Cort	born 20th Dec., 1760.
Conningsby Cort	" 12th Nov., 1770.
William Thomas Cort	" 16th Dec., 1771.
Eliza Jane Cort	" 21st April, 1773.
Harriet Ann Cort	" 22nd April, 1775.
John Harman Cort	" Jan., 1777.
Maria Cort	" 13th June, 1778.
Charlotte Cort	" 12th Oct., 1779.
Frederic John Cort	" 10th Oct., 1781.
Caroline Cort	" 18th Jan., 1783.
Richard Cort	" 20th April, 1784.
Louisa Cort	" 21st June, 1786.
Catherine Frampton Cort	" 24th Feb., 1790.

Of those thirteen, the son, Richard Cort, born 20th April, 1784, and three daughters, are the only survivors, their united ages being upwards of 290 years.

After ten years of success as a navy agent, during which period he amassed a considerable sum of money, Henry Cort was induced, about the year 1775, to relinquish his navy agency business and to prosecute a series of experiments in the manufacture of iron at Fontley, near Fareham, Hants, in partnership with one Adam Jellicoe, of the Pay-office. He erected a forge and mill on the estate of Mr. Delme; he purchased the premises and the goodwill of a business at Gosport, which, with the debts for iron supplied to the navy, were valued at upwards of £39,000. In his business of a navy agent, Cort had become well acquainted with the inferiority of the British and the superiority of the foreign iron, and he entered with zeal and enthusiasm into the attempts to improve the home manufacture of iron, so as to make Great Britain independent of foreign nations for the supply of this most important article. It is much to be regretted that no record exists of the steps by which Cort arrived at the series of processes constituting his invention; prudence would prevent the disclosure of the results of his experiments until after the patents should have been obtained, and recourse must be had to the specifications as the only authentic records of the invention.

Cort's first patent bears date the 17th January, 1783. It is for "A peculiar method and process of preparing, welding, and working various sorts of iron, and of reducing the same into uses by machinery, a furnace and other apparatus adapted and applied to the same purpose." The specification enrolled the 16th May, 1783, four months after the date of the patent, describes the process to be pursued in the manufacture of various enumerated articles, and affords the most con-

clusive evidence of the laborious detail with which the invention had been matured. Commencing with what are termed "large uses," such as shanks, arms, rings, and palms of anchors, it describes the laying bars of iron of suitable lengths, forged on purpose, and tapering, so as to be thinner at one end than the other, one over another in the manner of bricks in buildings, so that the upper bars everywhere cover the joints of those underneath, and thereby make a faggot, two bars wider than those which compose the beds, being laid at the bottom and top and bolted so as to be better laid on the anvil and receive the first strokes of the hammer; the faggot is bound together as close as possible. The system here described is now known by the technical terms of "piling" and "faggoting." The faggots so prepared by the system of piling to the amount of half-a-ton more or less, are to be put into a common air furnace and usually called a balling furnace, and there is brought to a welding heat at the same time with greater despatch than can be effected in a hollow fire with a blast. The giving this welding heat in a balling furnace according to the method and process specified, is stated to be part of the invention. The specification, after describing the method adopted where several weldings are to be made, concludes the part of the description by stating as follows:—"The whole is neatly finished under a large hammer without the use of either chaffery or hollow fire. And I find that the largest uses thus finished by me are in all respects possessed of the highest degree of perfection. I also have found that the fire in the balling furnace is better suited for its regularity and penetrating quality to give the iron a perfect welding heat throughout its whole mass without burning in any part, than any fire blown by blast, inasmuch that if bar or other massy iron is bound into a faggot of five or six inches diameter by an old cask hoop the sixteenth part of an inch in thickness, the one will acquire a complete welding heat and the other not be burnt or wasted, and the iron is welded to the centre instead of, as in the usual method practised being covered only with an incrustation." In the above is the announcement of the system of piling, faggoting, and heating, in an air or balling furnace, of iron to be forged by hammers into various uses, as a means of securing uniformity of constitution in opposition to the old system of heating in a hollow fire under a blast. The specification having remarked on the imperfect removal by the forge hammer of the impurities—earth, salt, and sulphur—describes a process of cleansing if the iron be in a dirty state, as conducive to producing iron of purer grain and more perfect texture proceeds to describe the working of the faggots by passing through rollers, and states as follows:—"and by this simple process all the earthy particles are pressed out and the iron becomes at once free from dross, or what is usually called cinder, and is compressed into a fibrous and tough state." Such is the simple process of manufacture producing a result which is thus stated:—"Accordingly, a bar of the worst ordinary iron in which the grains of metal are large and much separated by the impurities with which it is impregnated being passed through the simple operation becomes instantly of good quality, and two or more of the same bars or of any pieces of impure iron heated in the same manner, and passed through the rollers together, become at once welded into one solid body and meliorated into good tough iron, without being previously cleansed in the scouring barrel or otherwise. If the iron to be welded by this method is intended for plates of any kind, it is bundled or laid together,

before being put into the furnace, in the shape and size best suited to the use for which such plates are intended, and passed repeatedly through the common rolling and slitting mill rollers with flat surfaces till it acquires the requisite degree of thinness. If it be intended for flat or square bars, rods, hoops, or the like, as soon as welded and made sufficiently thin under the rollers, it may at the same heat be passed through the slitters, and from them again through the rollers, if needful, for proper uses. When the iron thus to be welded through the rollers is designed for bars, half flats or thimble iron, with feather edges, a groove of the requisite dimensions is made in the under roller, through which groove the iron is to be passed in the state of welding heat."

The specification also states:—"Much of the success of the operations described depend on the iron being properly cut, faggoted, banded, or placed together;" and that in mills of sufficient power, with rollers large enough to admit of grooves and collars for the purpose, very great sized iron may be welded in this manner as well as under the hammer, the heat being the same in both cases, and claims such process as his own invention, and put in use by him only. It is material to observe that Cort, in this specification, speaks of the rollers, furnace, and separate processes as well known; there is no claim to any of them separately, the claim is to the reducing of the faggots of piled iron into bars, and the welding of such bars by rollers instead of by forge hammers. This invention as then announced and described in the specification in the above terms is a faithful description of the manufacture as now practised. Cort's own language may be applied to the manufacture as practised after an interval of 75 years; the grooved rolls, whether of the rectangular, diamond, or double flanged shape, are the rolls described by Cort and used for the same purposes; each presenting a specific section through which the iron at a welding heat is constrained to pass, being unable to escape on either side, and becoming deprived of its impurities, condensed, elongated, and welded, precisely in the manner described by Cort. It should be remarked that Cort in this specification takes and treats bar-iron as then existing; this invention begins with and has reference to a method of making "uses," as they are termed, by piling, faggoting, and rolling, not to the manufacture of the bar from the cast-iron which forms the subject of the next patent.

Cort's second patent is dated 13th Feb., 1784; it is for "A new mode and art of shingling, welding, and manufacturing iron and steel into bars, plates, rods, and otherwise, of purer quality, in large quantities, by a more effectual application of fires and machinery, and with greater yield than any method before attained or put in practice."

The specification enrolled on the 12th day of June (four months after the date of the patent), relates to the preparing, manufacturing, and welding of iron from the ore, as well as from sow and pig metal, and also from every other sort of cast iron, together with or without scull and cinder iron and wrought iron straps. The furnace employed is the reverberatory or air furnace, hollowed or dishd out at the bottom, so as to contain the metal when in a fluid state. The furnace having been brought to a proper degree of heat, the fluid metal is conveyed into the air furnace, or the metal may be fused in the furnace, the doors of which are then closed until the metal is sufficiently fused, when the whole is worked and moved about by bars and other fitly shaped instruments through apertures, which operation is continued until an ebullition effervescence, or such like intestine

motion takes place, accompanied by the emission of a bluish flame or vapour; the operation is continued, as occasion may require, of raking, separating, stirring, and spreading the whole about the furnace till it loses its fusibility, and is brought into nature; the iron when so brought into nature is collected together in lumps called loops, of sizes suited to the intended purposes, and so drawn out of the doors or furnaces. The specification declares the above method and process of preparing, manufacturing, and working of iron, in substitution and instead of the use of the finery, to be Cort's invention, and never before used or put in practice by any other person or persons. The specification proceeds to state that the iron so prepared may be afterwards stamped into plates, and piled and worked in an air furnace; but that the method and process invented and brought to perfection by Cort is to continue the loops in the same furnace, or to put them into another air furnace or furnaces, and to heat them to a white or welding heat, and then to shingle them under a forge hammer, or by other machinery; and after having been shingled to the size of the grooves in the rollers are worked through the grooved rollers, in the manner in which Cort used bars or wrought iron faggoted, and heated to a welding heat; which manner of working any sort of iron in a white or welding heat through grooved rollers, Cort declares to be entirely his own invention. The following is the concluding paragraph of the specification:—"Iron and steel so prepared, made, wrought, and manufactured by such effectual application of fire and machinery, will be discharged of the impurities and foreign matter which adheres to them when manufactured in the methods commonly practised. The steel is of an excellent quality, and the iron will be found to be good tough iron in bars and uses, whether large or small, and in all sorts of merchant iron, whether it be made from metal of a red short or cold short nature; and blistered steel, whether made from iron prepared according to the above process, or from any other iron when faggoted together, heated to a white or welding heat, rolled in that heat through grooved rollers, according to the method invented by me, and slit through the common cutters, is equal to steel manufactured by forge and tilt hammers. The whole of which discovery and attainment are produced by a more effectual application of fire and machinery, as described by me, than was before known of or used by others, and are entirely new and contrary to all received opinions amongst persons conversant in the manufacture of iron; and the whole of my method may be completed without the necessity of using finery, charcoal, cokes, chaffery, or hollow fire, and without requiring any blast by bellows or cylinders, or otherwise, or the use of fluxes in any part of the process. The whole operation to be performed with one or more furnaces, according to the quantities or dispatch required."

On the 12th day of June, 1784, Cort had published in the specification of his two patents the processes of which he asserted himself to be the inventor. No one can peruse these records of his invention without being at once struck with the precision and completeness of the disclosure thus made to the world as to the processes by which the manufacture of bar iron and of its uses was to be attained. The specification of the second patent discloses the process of "puddling" precisely as now practised. And it will be observed here also that reverberatory and air furnaces, and rollers, and working instruments are treated and spoken of as things well known; the invention in respect of

these consisting in their adaptation and manner of application. It should also be observed that the improved blast or application of improved blowing machinery was wholly immaterial to Cort's invention, which required only the ordinary reverberatory or air furnace.

Cort, at the conclusion of his specification in the passage already cited, declares his practice to be "entirely new, and contrary to all received opinions amongst persons conversant in the manufacture of iron." That he should have to encounter detraction, disbelief, and opposition is the inheritance of such men; fortunately, however, his position in society, and the means in his control, enabled him to demonstrate beyond cavil the truth of his representations as to the improvements resulting from his combined processes in the manufacture of iron.

THE SEWING MACHINE. ITS VALUE.

No. III.

Few persons in Great Britain are aware of the immense value of the sewing machine trade either to those who use machines, to those who own them, to those who manufacture them, or to the public in general.

The running of a sewing machine is a remarkably healthful and pleasant employment. The erect attitude of the operator, the exercise of the lower limbs in giving it motion, its lively clicking, and the rapidity with which "band and gusset and seam" are sewn up—all tend to keep up the spirits and preserve the health. The hours of labour, too, are short. In this country operators work on an average only nine or ten hours a day. One firm in New York which employs about 200 machines and 400 young women, says: "The fatigue is so slight that our employes work the year round and continue in good health and spirits." An American lady, accustomed to use a machine in her family, writes: "My sewing machine is to me perfectly fascinating. My children leave their amusements for the sake of operating it. The laundress and the waiting-maid hurry through their duties to share that of the sempstress. Housekeepers may well exchange their pianos, which they never have time to use, for a machine which will relieve them of many hours of weary labour. Substituting, as it does, healthful exercise, and cheerful, rational employment for the soul-and-body destroying drudgery of hand-sewing, it should be hailed as '*Woman's Friend*.'"

Its introduction has tended to raise women's wages. In the United States the wages of operators range from 12s. to 83s. per week. In New York a woman has been known to make as high as £12 per week with two assistants to prepare and finish the work. In Great Britain the wages of operators range from 7s. to 30s. per week, (the average being probably about 12s. per week), "whereas a mere sempstress can hardly earn half this sum, and that, too, through long protracted labour." In the stay-trade, the stay-stitchers who did the cheapest kind of work could only obtain an average of 1s. 6d. or 2s. a week, but by the use of a sewing machine they can now earn from 7s. to 9s. a week.

But while the sewing machine has doubled the wages of one class of operatives, it has not perceptibly lessened the number of persons engaged in tailoring, bootmaking, shirtmaking, dressmaking, and similar trades. "It may tend to displace a portion of male labour, but at the same time it calls into existence female labour, and that, too, at an enhanced value."* More work is put upon clothing now than before the use of machinery. Even on the coarser garments worn by the middle and poorer classes there is or amental work, such as double instead of single stitching on shirts, and on the breasts and sleeves of coats. Besides, the lessened cost of production has greatly increased

* See Dr. Strang's Paper on "The Sewing Machine in Glasgow," read before the British Association, at Leeds, September 25, 1858.

the demand for ready-made clothing both for home consumption and for exportation to all parts of the world. The necessary consequence of this increasing demand for well-made clothing has been an increasing demand for female labour. Poor women now get better pay for lighter work than they did a few years ago, when Hood drew the sympathies of the world to the needlewomen of London by his inimitable "Song of the Shirt." At present the demand for sewing machine operators exceeds the supply, and with the farther extension of the use of machines we may naturally expect increased employment for females and an increase of their wages.

The amount of sewing done by a single machine in a day or week necessarily varies with the expertness of the operator, the kind of machine used, and the quality of the work to be done. With a good operator on a first-class machine, one thousand yards of straight seam, ten stitches to the inch, is said to be an ordinary day's work of ten hours. Ten dozen of shirt wristbands can be made in an hour. Fifty dozen collars, or eighty shirt bosoms with seven rows of stitching, are easily made in one day. Eight fine linen coats may be made in a day of ten hours, and thirty such coats are an average week's work for one machine.

This rapidity of production has, hitherto, served to increase the profits of the wealthy manufacturers who own machines rather than to reduce the price of the manufactured article. Almost all those persons who were so rich and so fortunate as to purchase machines two or three years ago have been gaining a profit of from 20 to 25 per cent. more than their competitors who were content to plod on in the old methods of doing business. In some kinds of goods, however, the sewing machine has reduced the price of the finished article. In New York the price of men's clothing and of ladies' gaiter boots has been reduced about 20 per cent. It is said that in London, bootmakers can buy machine-made boot tops 30 per cent. cheaper than those made by hand. The finished boots, however, have not fallen in price more than from 10 to 15 per cent. But not until the reduction in the cost of manufacturing has been followed by a corresponding reduction in the prices of the finished articles in every department of trade will the full value and importance of the sewing machine be sensibly felt by the whole community.

The profits of those who use machines cannot, however, be so large as the profits of those who make them. It is believed by many persons in America that the three firms who have monopolized almost the whole business in the United States have become so wealthy that they are able to control the Patent Office. The existence of this belief (although it must be unfounded) is the best evidence of the enormous profits made by American manufacturers. We have no means of obtaining information regarding the profits of manufacturing in England. Machinists, judging merely from the appearance of the finished machine, say that on machines sold from £20 to £30 the manufacturer's profit cannot amount to less than three-fifths of the selling prices; that is, on a machine sold for £25 the manufacturer has a clear profit of £15.

But while the profits of some of the patentees both in this country and the United States have been enormous, the public have gained largely from the use of their inventions. A single sewing machine in the least advantageous work is equal to the labour of six persons, and in many kinds of work, especially the finer and more difficult kinds of work, it is equal to the labour of from fifteen to twenty persons. Making every allowance, therefore, for the time machines are out of order, we may safely estimate that, on an average, every machine in Great Britain does as much as seven hand sewers. The 10,000 machines now at work in the country have added as much to its wealth as the labour of 60,000 persons beyond those actually employed would have added in the same time. And supposing these machines have been in use for only two years, they have already increased the

national wealth by one million and a half. During the same period, sewing machines must have added not less than fifteen millions to the wealth of the United States.

MONEY-MAKING AT THE ROYAL MINT.

No. VI.

It will be remembered that in our last week's paper on this interesting subject, the coining press-room was spoken of, and the rapid manner in which the conversion of prepared blanks of metal, whether of gold, silver, or copper, into sterling coin, under the force of the screw presses, drew forth its meed of commendation. There were allusions made also to the vacuum-chamber, by the aid of which the direct motion is given to those presses; and of this it will be perhaps well to give a little further explanation before advancing to the process of medal striking, and the manufacture of dies.

The vacuum-chamber was spoken of as an iron tube of considerable dimensions, and its use explained, but it was not stated by what means the vacuum in it was got up and maintained.* When Boulton and Watt in 1810 fitted up this portion of the Mint they had determined by actual experiment at Soho that the pressure of the atmosphere was the best possible power to use for stamping money, and they had accordingly devised what was called *secret* machinery on that principle for the Royal establishment. They, however, had calculated that for the effective working of the eight presses ordered for Tower-hill a ten-horse steam engine with two powerful air-pumps would be necessary. These were supplied, and the air-pumps, on the butterfly valve principle, 24 inches in diameter, and with a 28 inch stroke, worked from either end of a pump beam driven by a crank on the end of the fly-wheel shaft of the engine, were employed for a number of years—up to 1852, indeed—in exhausting the vacuum-chamber.

Things might have gone on in this primitive and very expensive manner up to this hour had not a very remarkable improvement been suggested in 1851 by a young mechanic, who had a few years previously been transplanted from the establishment of the Messrs. Rennie. This gentleman, whose name ought to be better known at the Treasury, conceived that if instead of using the one steam engine and the two pumps of Boulton and Watt for the exhaustive process, he were to attach to the beam of a 20-horse power engine, by Rennie—lately erected at a distance of some 220 or 230 feet from the press-room, and used for pumping water from an artesian well of great depth—a double acting air pump, and then carry a tube to connect it with the vacuum-chamber over the roof of the coining department, he might accomplish the same object at a vastly diminished expense. The proposition obtained little attention, although laid before the Sheil-Hume commission, until the advent of Captain Harness, R.E., who at once saw the practicability and value of the plan. In the beginning of the year 1853 the inventor of the new arrangement had the satisfaction of seeing it adopted, manufactured by Rennie, and put to practical use. It was found vastly superior in every respect to the old system. The extent of the vacuum gained by the well-constructed pump—which was of large comparative area and of short stroke, and which of course exhausted in the up and the down stroke—was much higher than could be obtained by the ancient "butterflies." The power obtained, too, was more steady and uniform, whilst the saving effected amounted to something like £200 per annum in fuel and wages—a saving still going on. Another great advantage which it gave to the Mint was, that it answered the purpose of a duplicate steam-engine. If the new pump became deranged, the old butterflies would be resorted to, and if the latter broke down there was the new arrangement in reserve.

This very neat plan of transferring so much of the power of the pumping-engine as is needed over the building and among the chimney-pots,

to the presses, without the aid of shafting or gearing or any apparatus susceptible of disarrangement, is a thing of which, as the author, the foremen of the coining press-room may very legitimately feel proud. The pockets of his fellow-countrymen have been spared to some extent by its introduction, if his own have derived no benefit therefrom. The extent to which the vacuum may be raised by the double-acting coining-pump is regulated by a steelyard relief valve placed on a branch of the vacuum-chamber, and a barometer gauge near it. If medals are in process of manipulation the vacuum is at its maximum point; if quarter-farthings, or *obolis*, then at its minimum. But every coin which has issued from the Mint for the last forty-nine years—and a great majority of the medals also—owe their sharp, clear, and beautiful impressions to the weight of the atmosphere. The air we breathe has, in short, coined all the money we use.

In touching upon this theme, it may be mentioned that a branch from the main artery for the circulation of air—the suction pipe to the vacuum-chamber—a branch from this descends to the vacuum-chamber of the weighing-room atmospheric engine, and thus creates the steady, never-changing motion which is given to the valuable weighing machines of which we have spoken.

It will be now completely understood that the vacuum-chamber is an important adjunct to the screw-presses; and, as the latter were left in our last chapter delivering themselves of finished coins at the rate, if all were in action, of 200,000 per diem, we may return to them after this dissertation on air. "Trifles light as air" have been alluded to by our never-to-be-forgotten bard; but, if he had known as much of the weight of that ethereal substance as the Queen's coiners, he would doubtless have substituted another simile. The gold pieces of the four bags have been followed by many, many more, and there, ranged in the butcher's trays without handles, are thousands and thousands of the metallic portraits of Her Majesty. These are, at the close of the day, placed on trucks, conveyed once again to the scales, weighed up carefully, folded once again in the little journey bags of 180oz., placed, in batches of eight bags or 5,608 sovereigns, in the trays, put into omnibus trucks, deposited in the stronghold, and locked. "Thanks!" says the officer, in turning the key upon perhaps 300,000 or 400,000—"thanks be to Providence, the wearing anxieties and cares of the day are over! Thanks, for losing sight of gold."

On the following morning at eleven, it is likely that a visitor to the Mint would see issuing into the "quadrilateral," or rather the quadrangular space, one or perhaps two of the omnibus trucks evidently bearing heavy burdens, and requiring each three or four men to propel them. They each contain, in fact, 70,100 sovereigns, weighing 18,003.06 ozs., and are destined to pass in—in very different form, shape, and value to that in which when bound for the melting-house they left it—to the central office. Arrived per tramway before alluded to, they are now "pyxed" by the senior officers. The pyxing is an operation into which we need at present perhaps not go into minute detail. It is a very ancient custom. Briefly, it may be said that a coin is reserved from each bag of gold—and the same may be said of silver—and placed in the pix, meaning a casket or chest. This latter, after the whole of the bags have had one coin abstracted from each and another to make the journey weights correct, is sealed with three seals and secured with three locks. The Master of the Mint holds one of these, the Chancellor of the Exchequer another, and the Queen's Assayer the third. The pieces of gold or silver so carefully preserved are kept till the trial of the pix, an annual performance—something after the sheriff's hob-nail arithmetic feat in usefulness—at which the fineness of the metal, as compared with certain trial plates kept in the treasury of the chapel of Edward the Confessor, in the cloisters of Westminster Abbey, is enquired into and a dinner partaken of. The pyxing at the Mint is a short operation, and after it the coins are ready

for delivery to the Bank. Bank clerks now arrive to check the journey weights in weighing with the Mint clerks. Bank porters come to put them into Bank chests, which are deposited in licensed carriers' carts, and fair receipt being given, the horses are compelled to move on, and away up the Minories, *en route* for the Bank itself, go the finished sovereigns. May those £140,000 which have just now gone, without any guard save a porter or two, be the means of doing an amount of unalloyed good, and may none of them be ever used for base purposes!

Returning once again to the coining department, we find that a change has come over the spirit of its dream. What are those large heavy discs of white metal—are they for crown pieces? No! they are intended for medals. They have been so far prepared in the same way that metal is prepared for stamping. They are of fine or virgin silver—that is, silver unalloyed—and have been rolled down from bars of the florin size—as given in Art. No. II. They have been also cut in the way explained with regard to ordinary coin. Now the treatment must, however, be different, and briefly that treatment shall be defined. The cut work is brought to the annealing-room in bags of 1000 medal blanks each. These are counted. They are next placed in open wrought iron pans and annealed or baked, then blanched, and now being distributed over recessed boards, their faces are scrubbed by means of scrubbing brushes, and with silver sand—the finest sand, that is—and water. This gives bright surfaces to them. Next they are dried by aid of box-wood sawdust, sieves, and drying stoves. And now they are ready to receive first impressions—in some cases very lasting as 'tis said—but in this of not half the value of past ones.

Removed to the press-room, counted, and supplied to a press tender, *rouleaus* are placed in a tube *à l'ordinaire*, the press is set in motion, the feeder does its duties, the dies kiss the pieces on both cheeks, the collar rises and falls, they are delivered into trays, examined by the press-room critics, and the whole operation resembles coining very much. But, alas! examine the embryo medals. They are not half struck. They may be intended for Crimean medals, but as yet there are but shadows of victory, and the well-known Roman warrior to be seen on the reverse, the noble head of the Queen is but outlined, and there are no letters. Evidently this is a preparatory step only? True; they have to be returned to the annealing-room, again baked, again blanched, again scrubbed, and again dried. Striking medals is a different and far more expensive process than coining money. The shadowy medals are again prepared and returned to the press-room once more. This time they must be daintily touched by the operator or they will be soiled, and perhaps require to go through all the stages again. Placed singly on a warm iron plate beside the press, to which one die only—the lower one—beautifully polished is attached, the operator takes them one by one, and puts them with his fingers on that die, taking especial care that the partly raised impression falls exactly into the corresponding cavities of the finishing die. He now places by hand also a steel collar of the size of the finished medal over the piece of silver—so as to encompass it—the collar being polished as the dies on its circumference. Next he “feels” the upper die upon the disc of silver, and makes its partially raised surface fit it. He now pulls one line, it closes the outer valve—another, it opens the inner one—of the press-pump. The screw with a plain block of steel fastened below its point has descended with terrific force upon the upper die, and the silver has suffered great compression. The press has rebounded, and is at rest. The upper die is taken off, the medal fitting the collar tightly, by force of pressure is lifted with the collar from the lower die, and behold you it is, as far as the Mint deals with it, perfect. It is pressed from the collar, examined by aid of a glass, and it is found that the soft silver with that last heavy blow has been forced into every interstice of the elaborately-engraved die.

It has become an exquisite work of art, and it requires but the clip, the clasp, the riband, and the name to make it worthy the acceptance of the bravest soldier.

INSTITUTION OF CIVIL ENGINEERS.

PREMIUMS, SESSION 1858-59.

The Council of the Institution of Civil Engineers have awarded the following premiums for papers read during the session recently concluded:—

1. A Telford Medal, to Michael Scott, M. Inst. C.E., for his paper “Description of a Breakwater at the Port of Blyth, and of Improvements in Breakwaters, applicable to Harbours of Refuge.”
2. A Telford Medal, to Robert Mallet, M. Inst. C.E., for his paper “On the Coefficients of Elasticity and of Rupture in Wrought Iron, in relation to the volume of the Metallic Mass, its metallurgic treatment, and the axial direction of its constituent crystals.”
3. A Telford Medal, to Henry Bessemer, for his paper “On the Manufacture of Malleable Iron and Steel.”
4. A Telford Medal and the Manby Premium, in Books, to William Joseph Kingsbury, Assoc. Inst. C.E., for his paper “Description of the Entrance, Entrance Lock, and Jetty Walls of the Victoria (London) Docks; with Remarks on the Form adopted in the construction of the Wrought Iron Gates and Caisson.”
5. A Watt Medal, to James Wardrop Jameson, Assoc. Inst. C.E., for his paper “On the performances of the screw steam-ship Sahel, fitted with Du Trembley's Combined Vapour Engine, and of the sister ship Oasis, with steam-engines worked expansively, and provided with partial surface condensation.”
6. A Council Premium of Books to Thomas Sebastain Isaac for his paper “On the Successful Working, by Locomotive Power, over gradients of 1 in 17, and curves of 300 feet radius, on Inclines in America.”
7. A Council Premium of Books to Matthew Bullock Jackson, M. Inst. C.E., for his paper “Description of the Gravitation Water Works at Melbourne, South Australia.”

ROYAL AGRICULTURAL SOCIETY'S MEETING.

WARWICK, Wednesday.

The following prizes for implements have been awarded:—

Judges: Messrs. W. Owen, C.E.; Jno. Brasnett, J. Clarke, J. Druce, J. Hicken, G. M. Hipwell, J. J. Rowley, J. Thompson, W. Tindal; C. E. Amos, C.E., consulting engineer. Stewards: Messrs. Barnett, Caldwell, and Pope.

Prizes: £4, Hornsby and Sons, light land plough; £3, Ransomes and Sims, ditto; £2, J. and F. Howard, ditto; £1, Hensman and Son, ditto; £2, John Eddy, turnwrest plough; £6, J. and F. Howard, general purpose plough; £5, Hornsby and Sons, ditto; £4, Ransomes and Sims, ditto; £2, Busby Agricultural Implement Company, ditto; £1, Hensman and Son, ditto; £3, Hornsby and Sons, heavy landplough; £2, J. and F. Howard, ditto; £2, Ransomes and Sims, ditto; £1 10s., W. Ball, ditto; £1 10s., Busby Agricultural Implement Company, ditto; £4, Messrs. J. and F. Howard, harrows for light land; £3, ditto; £2, Messrs. Page and Co., ditto; £2, Messrs. Mapplebeck and Lowe, chain harrows; £4, Messrs. J. and F. Howard, harrows for heavy land; £3, Messrs. Page and Co., ditto; £2, Messrs. Ransomes and Sims, ditto; £5, Mr. Bentall, cultivator for light land; £3, Messrs. Coleman and Son, ditto; £2, Mr. Cray, ditto; £5, Messrs. Coleman and Son, cultivators for heavy land; £3, Mr. Bentall, ditto; £2, Messrs. Ransomes and Sims, ditto; £3, Thomas Scragg, hand-power tile machine; £2, J. Whitehead, hand tile machine; £15, A. and W. Endington, draining plough and windlass; £3, F. Parkes and Co., bundle draining tools; £2, Mapplebeck and Love, bundle

draining tools; £10, J. Whitehead, brick and tile machine; £5, H. Chamberlain, brick and tile machine; £50, John Fowler, jun., set of steam cultivating apparatus, and balance four-furrow plough; £5, Trustees of Wm. Crosskill, field roller; £3, Messrs. Hill and Smith, field roller; £2, ditto, ditto; £5, Messrs. A. and E. Crosskill, clod crusher; £3, W. Cambridge, ditto; £2, Trustees of Wm. Crosskill, ditto.

Silver Medals.—Sidney Flavel and Co., kitchen range; Thomas Gibbs and Co., collection of agricultural plants, seeds, and grain, in great variety; Peter Lawson and Son, collection of plants, seeds, and grain; W. H. and George Dawes, patent atmospheric hammer; Humphrey Chamberlain, dry clay brick-making machine; Humphrey Chamberlain, plastic clay brick-making machine; Burgees and Key, grass-mowing machine.

Law Case.

COURT OF CHANCERY, Lincoln's-inn, July 8.—(Before Vice-Chancellor Sir W. P. Wood.)

THE PATENT TYPE-FOUNDING COMPANY (LIMITED) v. RICHARD.

This was a demurrer. The bill was filed to restrain the infringement of a patent for “improvements in the manufacture of type and other raised surfaces for printing,” which had become vested in the plaintiffs by assignment from John Robert Johnson, the original patentee. The patent was granted in 1854, and the specification contained the following statements:—“In the manufacture of type and other raised surfaces for printing it has been usual for the most part to employ compounds of lead and antimony as the metal for casting the same, and in some cases a small percentage of tin has been added. Now, the object of my invention is to obtain harder, tougher, and more enduring type, and by employing tin in large proportions with antimony, and to greatly reduce or wholly omit the use of lead with such metals when making type, by which means the type produced is so hard, tough, and enduring as to allow of its being used as a punch on the ordinary type metal now used, and the best proportions I am acquainted with are 75 of tin and 25 of antimony, but this may be to some extent varied; and when lead is also used I find that it must not exceed 50 parts in 100 of the combined metals employed, for if the lead be employed in much larger quantity the hardness and toughness of the alloy rapidly decrease, and the alloy then approaches the ordinary type metal in its properties, notwithstanding the presence of a considerable quantity of tin. When the antimony is tolerably pure, the best proportions are as given above—one part of antimony to three of tin or tin and lead; but when it contains other metals I find that the quantity of antimony should be diminished, or which is preferable, the metal should be repurified. If this be not attended to, the alloy, though of great hardness, does not possess the tenacity or hardness necessary for type of extreme durability.”

The defendants, against whom a case of having infringed the patent was alleged in the bill, had put in a demurrer, on the ground that the specification as set out in the bill was so vague as to render the patent void, and, at all events, to deprive the plaintiffs of any title to relief upon it in equity.

Sir Hugh Cairns, Mr. Webster (of the common law bar), and Mr. Druce appeared in support of the demurrer; Mr. Bolt and Mr. Bowring (with whom was Mr. Hindmarch, of the common law bar) were for the plaintiffs.

The VICE-CHANCELLOR said that the question was whether the specification was so clearly and manifestly bad that it would not enable workmen to carry it into execution. The invention appeared to be definitely stated, assuming that something further might come out in evidence. Was there any vagueness because the specification stated that the precise proportions might be varied? Upon a patent depending upon proportions the patentee was not bound to limit his claim entirely to those proportions. The vital property of the patent was a large proportion of tin, as contrasted with antimony, and, though some slight variation might be made in the proportions, yet that would not avoid the patent. Evidence might be produced as to the validity or invalidity of the patent before a jury, but at all events the patent, as stated on the face of the bill, was not void for indefiniteness. The demurrer must therefore be overruled.

Sir HUGH CAIRNS obtained leave to file a plea at once, leave being requested (after putting in a demurrer) for resorting to this mode of defence, which is technically known as a “second dilatory.”

FWLER'S STEAM PLOUGHING APPARATUS.

PLAN OF WORKING.— On the left is the Engine and Windlass, the Water-cart, and directly opposite to them the Anchor, and between these two the Plough is pulled backwards and forwards, one end of the Plough being alternately in the air and the other in its work.

FOWLER'S STEAM PLOUGHING APPARATUS.

FIG. 1.—SELF-MOVING ANCHOR.

A FEW weeks ago we gave a description and illustrations of the main portions of Mr. J. Fowler's apparatus for ploughing land by steam power, noticing the successive improvements he has made in it from the time he first exhibited it, and the very great degree of simplification he has at present attained in its construction. These improvements may be shortly stated to consist, first, of a better mode of applying the power; secondly, the lightening and cheapening of the apparatus; and, thirdly, the improvements made in its details, which cannot be separately enumerated, but which, taken collectively, are of vital importance, as upon the mode of carrying them out depend its durability and efficiency. The difference between good and bad detail frequently constitute all the difference between a machine made only to be looked at, and one which will bear to be daily worked. The great success of Mr. Fowler's apparatus at the trials which have been made during the present week at Warwick, induce us now to give yet a fuller description of it in its present form.

The first improvement—viz., that in the mode of applying the power, is one of very great importance. Instead of laying a rope round the field, as was done at Chelmsford in 1856, the engine and windlass are now made to work themselves along one side of the field as the plough performs its work, the anchor doing the same at the opposite side, as shown in the accompanying large illustration, the plough being worked between the engine and the anchor. Again, the rope being now passed over two grooves, instead of being wound on a barrel, as formerly, is another

step of much importance, especially as it saves a considerable length of rope. Next, the adoption of steel instead of iron rope has effected a great saving in wear and tear, which saving is further increased by passing it round large (4 feet) pulleys instead of small ones as formerly. As we have already explained in our last article, the windlass is now permanently combined with the

cent construction. We are now enabled to give an illustration of the latter, which is shown in Fig. 1. The frame is made entirely of wrought iron, the winding-forward drum being placed upon an upright spindle; and the machine so constructed with shafts as to be capable of being worked round any ordinary bend in a hedge. The side strain is well borne by the cutting discs or

wheels fitted to the machine, which is balanced by having a box filled with earth fixed at the side opposite that from which the wire-rope passes off. The forward motion is accomplished by the friction of the wire-rope on the four-feet pulley, to which is attached a drum for winding up a rope stretched along the headland and fixed to the ground.

The water-cart, which is drawn along with the engine, is made circular, and of wrought-iron, and is shown in Fig. 2.

It is used also for conveying the wire rope from place to place, and for this purpose is fitted with a fly-wheel and handle for winding the rope up upon it. The cart is made to contain about 150 gallons of water. Fig. 3 shows two of the rope "porters," with the rope running over the pulleys, as it does when in use.

Several of these porters are used when the field to be ploughed is of great length, in order to keep the rope as much off the ground as possible, thus to prevent unnecessary wear, and to economise the power required to work the apparatus.

We have before illustrated Mr. Fowler's balance-plough, but the accompanying illustration, Fig. 4, shows the application of scarifier irons to the same

engine, which, by aid of pitch wheels and chain, is made capable of moving itself by steam from field to field, only requiring to be steered by one or two horses, which is easily done, and avoids much of the complication attending ordinary steering apparatus.

FIG. 3.—ROPE PORTER.

In our former article we gave an illustration of an anchor used for some time by Mr. Fowler; but, as was then stated, not one of the most re-

frame work, the plough bodies being removed. Instead of attaching scarifier irons, the breasts only may be removed and shut, and blunt mould boards

FIG. 4.—SCARIFIER PLOUGH.

FIG. 5.—TRENCHING PLOUGH.

substituted in their steads, when at one operation a perfect fallow may be made. Fig. 5 shows one-half of a balance plough frame, with subsoil irons attached. We have now given illustrations of the whole apparatus used by Mr. Fowler, and which may be seen in operation at the Royal Agricultural Society's Show at Warwick, where agriculturists will have had an opportunity of verifying the statements we have made with regard to its simplicity and efficiency. The cost of ploughing by steam was stated in our last article, the results given being from trials by the Society's engineer. Estimates have, however, been made by several persons, and the several conclusions arrived at are that from 7s. to 10s. may be fairly put down as the cost of steam ploughing for different classes of land, and from 9s. to 18s. for double trenching the soil. These accounts, be it remembered, include every expense, wear and tear, interest of capital, &c., and compare very favourably with home labour. We insist that after so persevering a course as that which Mr. Fowler has taken, he should at length reap the reward of his labours. They have been most arduous, very costly, and such as nothing but a firm conviction that success was attainable, and a determination to obtain it, would have enabled him to overcome.

BOAT-LOWERING APPARATUS.—Mr. Clifford has forwarded to us—but too late for publication this week—a reply to the letter of “Nauticus,” which appeared in our last impression. This we hope to insert in our next, but in the mean time as the letter of “Nauticus” contained a statement relative to an accident to a boat's crew of the Oracle, which, if not immediately replied to, might operate seriously to Mr. Clifford's injury, it is only right that we should state that Mr. Clifford produces in contradiction to the charge letters from Messrs. Green and the Captain, which affirm “that there was not the slightest blame attached to her lowering gear,” and furthermore, “that where it has been fitted in Messrs. Green's ships it has given general satisfaction.”

THE MAGNETISM OF SHIPS.

By F. J. EVANS, Esq., Master R.N., F.R.A.S., Superintendent of the Compass Department, Admiralty.*

I HAVE to bring to your notice, and under review, the valuable labours, still in progress, of a committee formed at Liverpool by various gentlemen connected with the vast shipping interests of that port, and working also under the auspices of the Board of Trade, to collect observations and make experiments on the condition and distribution of magnetism in iron-built ships, and the general system of compass correction and management.

Two or three disastrous shipwrecks, clearly traced to compass errors, occurring about the time that the iron navy of Liverpool was rapidly expanding, gave rise to various conflicting opinions on the safety of their navigation, and particularly on the subject of compass-compensation by magnets; these questions were discussed in various periodicals, and also at the British Association for the Advancement of Science, held at Liverpool in 1854: hence arose the formation of the Liverpool Compass Committee.

The publication in 1857 of the first and second reports of that body to the Board of Trade, and presented to both Houses of Parliament by command of Her Majesty, enables the observations relative to the theory of the magnetism of ships to be extended, not only in confirming what has been already advanced, but in giving some more general views of its character and distribution, particularly in iron-built vessels.

A striking feature in these reports is, that the researches of the various authorities already quoted, and their exposition of the laws of magnetic action on ship-board, have received ample confirmation from the various observations collected and experiments undertaken by the committee. In the opening page of the second report they observe, that it has been “proved, too, most decisively, that the deviations of the compass on board iron ships, when properly ascertained, are

not of that irregular and erratic character which many cards of deviation might lead one to suppose, but that they accord most closely with the deductions of theory and experiment, as exemplified in the works of the Astronomer Royal and Mr. Archibald Smith.” And again, at p. 24, in alluding to certain fluctuations in the amount and direction of a ship's induced magnetism, — “These fluctuations do not appear, however, to affect practically an authoritative statement which has already been supported by the committee, and which, as it forms the key to the connection and calculation of compass deviations, cannot be too earnestly repeated; namely, that a ship's magnetism for any given place may be very closely represented by a permanent polar magnetic force in combination with a quadrantal force, or one changing its deviation in each quadrant as a ship is swung round.”

Among the various philosophers who, during the present half century—a period noted for the progress of theoretical and experimental research—have grappled with the perplexing and, it may be said, uninviting science of magnetism, none more perseveringly worked for practical ends than the late Rev. Dr. Scoresby, and to him is due the enunciation of the notable facts, that the distribution of magnetism in an iron ship depends on the direction of the keel and head while building with reference to the magnetic meridian; and that this original magnetism is subject to great

changes after launching, and also from other extraneous causes. The following from among the results of his investigations, as bearing on the subject, are worthy of extract. — (*Magnetical Investigations, by the Rev. Wm. Scoresby, D.D., vol. ii. 1852, pp. 330—343.*)

1. That ships built of iron in place of timber and plank obtain necessarily an extremely high degree of magnetic development from the elaborate system of percussive action, as well as from the bending of the plates and bars, during the progress of their construction.

2. That the dominant magnetism thus developed is of the retentive quality, a quality remaining whilst terrestrially sustained by consistency of position, and otherwise, also, in relations inaccordant with terrestrial influence, whilst the ship remains free from mechanical violence or other magnetically-disturbing force.

3. That in each iron ship there is a special individuality of the magnetic distribution, depending essentially on the position—characterised by the direction of the keel and head—whilst building, and peculiarly on the deviations from uniformity in the placing of occasional heavy masses of iron.

4. That, after being launched, percussion, vibration, or the straining of the general frame of iron-built ships, must tend to equalise the relations of the ship's magnetisms with those of the earth; and that the state of equalisation or approximation thereto will be hastened and advanced accordingly as the quantity or intensity of mechanical violence is increased, and accordingly as the ship's head is kept pretty steadily in the same direction.

The accompanying diagrams represent, according to Dr. Scoresby, the theoretic magnetic condition of iron ships built in England, with the dip of the needle from 68° to 70° N., previous to being launched.

The confirmation of Dr. Scoresby's views will be seen from the following extract: “The records of the committee no longer allow a doubt as to the connection which exists between the direction of a ship's original magnetism and her position when upon the building slip. In all the ships which have been examined, the north end of the compass-needle invariably deviated towards that part

* Portion of a paper recently read at the United Service Institution, and published in the Journal of that Society.

of the ship which was farthest from the north while she was building, if the compass was placed in a central position, and free from the influence of individual masses of iron.*

The reports also further proceed to show that the characteristic features of the original magnetism of an iron ship, by which is meant the magnetism dependent on her direction when building, and the effect on a compass when she is swung, presuming that the needle is not influenced by iron bulk-heads, or proximity to the stern-post, rudder-head, or other masses of vertical iron controlling the magnetism of the hull of the ship, is as follows:—

In an iron ship built with her head to the north, or nearly so, there is no apparent attraction of the needle towards either side while she lies in a north or south direction: but with her head in all other directions there is a strong attraction towards the stern.

With ships built head to the south, the same principle will apply, the deviation being then towards the bow.

When built with head to the east, the deviation is towards the starboard side, (the south in building) and when built with the head to the west, to the port side (the south in building): [this deviation must be considered as only due to a differential action, for if a compass be placed near the top sides of such ships either internally or externally, the north end of the needle (in north magnetic latitudes) is attracted; one side, however, attracts the needle more strongly than the other, and that is the side which was furthest from the north: when the ship was building, as above stated.] In these vessels if placed in an east or west direction, the north end of the needle will tend to the bow or stern respectively according to the direction in which lies the greater mass of iron.

In ships built in intermediate positions the preceding characteristics are combined; thus, if built with head to the N.E., the attraction will be aft and to starboard; with the head to the N.W., aft and to port. If the head be S.E. or S.W., the attraction will be forward and to starboard, or forward and to port respectively.

The amount of original magnetism appears to have relation to the size of the vessel, or the quantity of iron used in her construction, and is thus illustrated:—"In a ship of 400 tons, built head to east, if a compass be carried fore and aft on the middle line, about three or four feet from the deck, the deviation may be 10° or 12° when her head is north or south. In a ship of 1,000 tons it may under the same conditions be 25° or 30° , or more, depending to some extent on the breadth of the ship."

From a consideration of the foregoing illustrations, we may at once predicate the character of an iron ship's deviation from a knowledge of the direction of her keel and head when building, or, *vice versa*, from having her deviation table we may infer the direction in which she was built: the accompanying table illustrates generally these conditions. Thus if

Approximate direction of ship's head (magnetic) while building is,	Maximum Easterly deviation when ship's head is near.	Maximum Westerly deviation when ship's head is near.
North.	West.	East.
N.E.	N.W.	S.E.
East.	North.	South.
S.E.	N.E.	S.W.
South.	East.	West.
S.W.	S.E.	N.W.
West.	South.	North.
N.W.	S.W.	N.E.

We have now arrived at an important feature of the inquiry—the alteration in the ship's magnetism after launching—and which would still appear to require an extended series of experiments to elicit more precise information. Numerous examples are given by the committee, but derived more from information communicated than

* This was exemplified by diagrams, which represent the magnetic character of various vessels as determined by actual experiment at Liverpool while they were in dock, and which will appear with the conclusion of this article, probably in our next number.

from direct experiment; still there is a notable example deduced from the latter in the case of the ship Royal Charter, which will be hereafter alluded to. The conclusions arrived at are thus given:—

This original magnetism of an iron ship is frequently very permanent as regards direction, but is believed to undergo rapid changes in its amount, both in reality and in its apparent effect on the compass: the most striking change being at and immediately after launching, and during the first voyage. It is usually more evident in a steamer than in a sailing vessel. There are cases in which the deviations in a steamer have changed so much as two points in the first two days at sea, while afterwards the change has not been more than 3° in as many months. In new sailing ships the change is generally, but not always, more gradual, and extends over a longer period. A change of 10° to 15° is not infrequent.

Again, Under some circumstances considerably more than one half of a ship's original magnetism, or rather that part of it which affects the compass, may be lost, or may become balanced in the course of a year.

And, After this early reduction of a ship's magnetism has taken place, the remaining portion, as far as may be judged from examinations made in the same place, and under the same circumstances, appears to be comparatively permanent.

In confirmation of this comparatively permanent condition of a ship's magnetism the committee give a striking example in the case of the ship Great Britain; and it may be permitted me to express my opinion, having had the opportunity of inspecting deviation tables of most of the iron vessels in H.M. navy, extending over many years' observations, that from this evidence also their permanent condition appears to be the rule.

The committee thus report on that well-known iron ship the Great Britain:—

This extraordinary ship has been stranded, and strained, and altered; has traversed both hemispheres, and been very many years in active service; yet her lines of no deviation are now much the same as Dr. Scoresby would indicate them to have been when she was upon the stocks. Yet how small is the change! a proof, apparently, that no circumstances can permanently conceal or greatly alter the direction of an iron ship's original magnetism.

[Illustrations in support of these views are given in the Committee Reports of the lines as taken in a graving dock, January, 1856; again in December, 1856, after being for some weeks head N.N.E. in the same graving dock; as they appeared two days after with her head in the opposite direction; and again as determined twice in January, 1857, after undergoing constant hammering in almost every part for forty-three days.]

The most instructive case of the rapid changes of magnetism in a newly-built iron ship is illustrated in the case of the ship Royal Charter, whose deviations were carefully obtained prior to leaving England in January, 1856; at Melbourne in Australia, in May, 1856; and again on her return to Liverpool in August of the same year. These changes are well exemplified by a comparison of the values of the five co-efficients alluded to; the results being selected from an extended series of observations, as made with an Admiralty standard-compass specially placed in aid of the experiments.

We see here very distinctly the permanency of the quadrantal deviation as represented principally by the co-efficient D; and the gradual diminution of the sub-permanent magnetism, or polar-magnet deviation, in the co-efficients B and C.

Subsequent experiments in the Royal Charter indicate that the sub-permanent magnetism is approximating to its original amount; but, as some alterations have been made in the ship's fittings, the comparisons are not strictly identical; they are nevertheless well worthy of attention.

Liverpool in Sep-tember, 1856,	A	B	C	D	E
after alterations—	0 19,	+ 1 13,	- 8 33,	+ 6 0,	- 0 19
Liverpool in Octo-ber, 1856...	- 0 9,	- 4 55,	- 14 0,	+ 6 41,	- 0 9

Enough has now been advanced to show the valuable nature of the investigations under review, but on the subject of the changes of original magnetism in newly-launched iron ships there appears to be ample scope for further inquiry, both as to the possibility of there being some regular law of change, as also as to the probable time required for the development of its final permanency of character. The alarming change alluded to in the reports by the committee of "cases in which the deviations in a steamer have changed so much as two points in the first two days at sea, while afterwards the change has not been more than 3° in as many months," is from its amount and irregularity sufficient to embarrass the most careful navigator; it is certainly to be hoped that the cases on which the statement is based are exceptional, and arising from the injudicious selection of a position for the compass (probably from close proximity to some ponderous mass, especially of vertical iron). I am certainly disposed to view them in this light from a consideration of the results obtained in the Royal Charter.

An important feature in the navigation of iron vessels, and one at the same time of a perplexing character to the navigator, are the changes of deviation of the compass arising from the heeling of some ships.

In wood-built vessels the errors from this cause may be considered as in general too small in amount to be appreciable in practice, unless the compass is in close proximity to the guns or other masses of iron; but in iron-built vessels the results are not unfrequently of sufficient magnitude to call forth unceasing attention and vigilance. Our information on this head is for the present very incomplete; but some few leading points can be traced, sufficient to place the seaman on his guard and to draw attention to the general characteristics. Messrs. Rundell and Towson, the secretary and honorary secretary to the Liverpool committee, who have paid great attention to the subject, and made various experiments, are of opinion that heeling affects to the greatest extent ships that are built with their heads to the north or the south; and that the effect on the former is to draw the north end of the needle to the weather side, the deviations reaching their maxima when the ship's head is north or south (by compass), and having little or no effect when the ship's head is east or west. In ships built with their head to the south, the north end of the needle will be drawn to the lee side, the maxima and minima deviations observing also the same conditions as those just described.

I propose now to enter somewhat briefly, as I have trespassed long on your attention, on the vexed question of mechanical adjustment for compasses.

Much controversy has taken place on the propriety and indeed safety of applying an antagonistic force to neutralize that of the disturbing effects of the iron in the ship: our highest magnetic authorities differ on the point, though agreeing in the main theoretical principles as to the nature of the magnetic disturbances. The Astronomer Royal is strongly in favour of correcting the deviation of the compass by opposing forces of magnets and soft iron. Admiral FitzRoy, General Sabine, and Mr. A. Smith, supported by numerous nautical authorities, consider such corrections dangerous—except within certain limits, such as coasting navigation—and prefer a superior compass, to be considered a standard, fixed in an elevated position, convenient for careful bearings, as far removed as possible from the disturbing influence of iron, and using the binnacle compass merely as a guide to the man at the wheel.

The opponents of the system of compensation urge that it is defective in principle and dangerous in practice; defective in principle so far that it has not stood the test of experience in distant voyages to the southern hemisphere, and dan-

gerous inasmuch as it inspires the unskilled and unwary seaman with confidence in the stability of that which is not proved to be stable, and places in his hand a power over the action of the compass-needle which he cannot control and of whose strength he is ignorant.

The advocates, on the other hand, contend that a fertile source of error in navigation arises from the unskilful use of the deviation tables, the corrections being frequently allowed the wrong way, by which the original error is doubled; also that the tables do not provide for changes of the ship's magnetism caused by change of geographic position or other circumstances; and again from the want of directive power of the needles under certain conditions of large deviation due to the ship's iron, combined with the earth's directive or horizontal force being small, as in the higher latitudes; which deficiency of directive power magnet compensation would remedy.

There are just reasons in all or many of these arguments, and the question appears more to resolve itself, as my subsequent remarks will tend to show, into one of application under varied but certain conditions.

(To be concluded in our next.)

THE SMALL ARMS FACTORY AT ENFIELD.

THE very complete and extraordinarily interesting machinery of the Small Arms Factory at Enfield Lock has been the theme of eulogium amongst mechanical men for some little time past; and anything in connexion with it cannot but be noteworthy, in these times, to the general public. So perfect are the contrivances there for the purpose in view—the rapid production of small arms of unerring accuracy—that it was thought by some that the force of invention could no further go. Every manipulative process, from the rough branch of the tree and the crude product of the forge, to the finished stock and truly bored and rifled barrel, together with all correlative details pertaining to them, seemed to have been successfully provided for. Machines accomplished almost everything, whilst attendants but looked on, and visitors were amazed.

As it has been often said, however, "Nothing of human creation is quite perfect," so it has proved with regard to the machinery of the Small Arms Factory at Enfield. Improvements have been recently, and are now being made in the automaton machines at that place. There appears to be an emulative spirit at work among those engaged near them, which is sure to be productive of advantage, especially as it seems to be encouraged by those in power. There was one portion of the rifle which the manufacturers of Birmingham had pronounced beyond the reach of machine labour at all. This was the lock. Inventions and improvements, however, on the part of some of the foremen of Enfield have brought this important portion of the implement of war quite within machine range; and it is, indeed, completed almost without a touch from the hand of the mechanic. To Mr. C. F. Hayes, Manager of the Lock and Screw Department, belongs mainly the credit of this remarkable, and for the country very economical change; and certainly Col. Dixon, Superintendent of the Establishment, performed but a graceful act when, on Saturday, the 25th ult., he presented Mr. Hayes with a War Department prize of £30 for his ingenuity. The lock of an Enfield rifle is an intricate piece of work; the principal parts being the "bride," the "swivel," the "tumbler," and the "hammer." It was in relation to these minute but yet consequential details that Mr. Hayes displayed his skill. On the same interesting occasion, we learn that Colonel Dixon, who was attended by J. Gunner, Esq., Inspector of Small Arms, G. Munro, Esq., Storekeeper, and Mr. Barnes, presented second and third prizes of £17 and £13 to Messrs. H. B. Hague and G. Williams, of the "Furniture" and "Sight" Departments respectively, for inventions in connexion with their branches of small arms manipulation.

We record these facts because they are interesting and satisfactory, and because we are anxious that in all cases there should be an appreciation of services rendered by *employés* of the Government. It has been too much the practice hitherto for those in authority to becloud the merits of those beneath them, and in many cases even to decorate themselves with laurels earned by others.

Colonel Dixon, who is highly respected, and not more for his professional ability than his urbanity, has offered an excellent example in his late distribution of prizes at Enfield; and on behalf of all who are in positions similar to those of Messrs. Hayes, Hague, and Williams we desire to see that example followed largely. It is not improbable that ere long some particulars as to the rate of production at the Enfield Small Arms Factory may be given, with other facts in relation to the place.

DUNN'S PATENT CARPET CLOTH.

WE had occasion a short time since to allude to this beautiful material, and the great interest which has been excited amongst manufacturers generally has fully corroborated our first opinion of it. That it will eventually supersede many of the articles now in use, from its great proximity to the appearance of carpet, in lieu of the present dirty substitutes, there can be but little doubt. The patentee, who was formerly with Messrs. Goodyear and Co., and now connected with the eminent firm of Messrs. Blackwood and Co., of Broad-street Hill, has favoured us with many details of this process, which is obviously destined to play a worthy part in the history of manufactures. It is certainly suggestive of a vast number of industries, as each individual interested in his own peculiar notions sees, even in its present position upon the mere threshold of usefulness, some one or other profitable application. We are informed that Mr. Dunn has discovered a mode of vulcanizing colours—a desideratum which has occupied the attention for years past of some of the greatest chemists of Europe, and which, according to the scientific journals of the continent, was conceived to be unattainable.

THE STEAM RAM.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—By the newspapers we are informed that it is determined to build a monster vessel, designated "The Steam Ram," which, from the description of her, is intended to run over or run down all swimming craft that she may upon the ocean obtain sight of. Little short of £500,000 is to be expended upon her construction and equipments. It may be presumption in me to question the prudence of such undertaking, or the prowess of this sea monster, but I would ask, How is she to run, with a chance of swimming, among submarine charges of gunpowder or explosive composition? Suppose, for instance, that she pursues a steam-vessel—a mite of a thing in comparison—armed with submarine explosive shells, suspended by buoys at any desired depth below the surface of the water; these shells may be regarded as submarine vessels in tow. The steamer so armed, upon being pursued, launches overboard one or two more of her shells, towing them by suitable ropes or chains. On comes the monster ram, and runs into contact with one or more shells, which are so constructed as to explode, by self-action, only when in *hugging contact* with any vessel that may be the object of attack or destruction. Now the result of such a collision would, I confidently predict, be the bilging of "The Steam Ram" to an extent beyond repair; down she would, in all probability, quickly go; and with her a crew of not less, perhaps, than a thousand men. In all earnestness would I commend this matter to the careful consideration of those whom it may concern. I remain, Gentlemen, your obedient servant,

JOHN HARVEY, Captain R.N.

Sandgate, Folkstone, July.

[We do not quite perceive what conclusion it is towards which Captain Harvey would conduct us. Does he intend to imply that the new iron steam

ship will be more exposed to submarine attack than any other large ship? And if not, would not his argument have equal cogency if directed against the building of any and every kind of large war-ship?—EDS. M.M.]

SCREW PROPELLERS.

Captain Beadon, R.N., sends the following:—

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—You remark in your magazine of the 1st instant in reference to recent experimental trials of screw propellers: H.M.S. *Doria*, that proof had been given that a blade formed of a fine flowing curve throughout would be more successful, as had been proposed by Sir Howard Douglas. I hope you will do me the justice to state that this is no other than the first and original form of screw propeller designed by me in 1834 to Captain Ericsson, keyed to a horizontal submerged shaft connected with steam power, and two years before patents had been obtained for the mangled principle either by Smith or Ericsson. On my return from China, in 1842, I again urged its adoption. In 1845 I patented it through Messrs. Robertson and Co., whose opinion you will see expressed in ten minutes reading, the last ten pages of which I devoted to illustrate the advantage of a curved blade, and its history, after actual experiment under steam power. In 1851 I exhibited the volute principle by a model at the Great Exhibition for six months, with a challenge appended. I am, yours faithfully,

GEORGE BEADON.

Crichtarrow, Taunton, July, 1859.

GRIFFITH'S SCREW PROPELLER.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—In your last publication I find two letters from Lord Carlingford claiming the merit of being the inventor of my patent screw propeller.

My first patent, including the large boss and tapered blades, was taken out in 1849; at that time I was not aware there was such a person as Lord Carlingford in existence and if his lordship will read my specification of 1849 he may satisfy himself that I could not have taken any idea from him, and I am ready at any time to try the validity of my patent with him.

I am, Gentlemen, your most obedient servant,
ROBT. GRIFFITHS.

69 Mornington-road, N.W., July 15, 1859.

THE GREAT EASTERN.

GENTLEMEN,—Your correspondent "A Reader," says that the employment of paddle-wheels in this ship destroys her usefulness as a sailing vessel. This is erroneous. The paddle-wheels are narrow, and small in diameter, in proportion to the vessel, and, being provided with disconnecting gear, I doubt whether two-horses power would be consumed in turning them when the vessel is going 10 knots under sail alone. The crew would consume a little more power, were it not provided (as I believe it is) with a small engine to keep it going just sufficiently to prevent drag. Although she will carry low rigging for her size, I think she will not only prove very handy under sail, but will, as a sailing vessel, bear any other sailing vessel in existence. I am, Gentlemen,

Your very obedient servant,
T. MOY.

1 Clifford's Inn, 12th July, 1859

NOTICES.

The MECHANICS' MAGAZINE will be sent free by post to all subscribers of £1 ls. 8d., annually, payable in advance. Post Office Orders to be made payable to R. A. Brooman, at the Post Office, Fleet Street, London, E.C.

TO ADVERTISERS.

All Advertisements occupying less than half-a-column are charged at the rate of 4s. per line for any number of insertions less than 13; for 3 insertions, 4d. per line; and for 52 insertions, 3d. per line.

Each line consists of 10 words, the first line counting as two. Wood-cuts are charged at the same rate as type for the space occupied.

Literature.

An Essay on Hydrographical Engineering, as applicable to Floating Sea Barriers, Harbours, Batteries, Coast Defences, and Naval Fortifications. By Captain ADDERLEY SLEIGH, K.T.S., F.R.S.L., &c. With Illustrations. London: Peller, 31 Poultry; and Stanford, Charing Cross. 1859.

WHEN we inform the reader that this work consists of only 58 pages of large leaded type, in a green paper wrapper—that its “illustrations” are lithographs from some of the roughest pen-and-ink sketches that we have ever seen—and that the main topic of the whole is a certain invention of the author’s—he (the reader) will scarcely be induced to pay for it the sum of *ten shillings*, which Captain Adderley Sleigh modestly asks for it. We cannot look at this pamphlet without being instantly reminded of a work which, a short time since, passed under the notice of ourselves and our readers—Mr. Calver’s pamphlet on the “Wave Screen” (J. Weale, 1858). The objects of both pamphlets are identical inasmuch as they were both written in advocacy of certain forms of sea barriers; but Mr. Calver’s is not only the sounder, and in all respects the better book, but it is also, by very much, the cheaper of the two. There is also a great difference between the structures recommended by these two officers. Captain Sleigh advocates floating, Mr. Calver fixed, breakwaters: the former would incline their surfaces; the latter would make them vertical. There is much to be said in favour of, and much against, the plans of both. But there can be no question as to the relative capabilities of the two writers to discuss the subject. Captain Sleigh moves over the surfaces of many things. He was once in the Royal Navy; subsequently he joined the Land Transport Corps; now he is in neither. He is, moreover, the author of “A System of Military Portable Telegraphic Communication;” also, of a treatise on the “Nautical Re-organisation of the Mercantile Marine, and Manning the Navy by Voluntary Enrolment;” also, of a brochure on “The Amazon, or Suggestions for Preventing the Loss of Steam Ships;” also, of a set of “Climatic Statistics of Great Britain,” &c., &c. He has now alighted upon batteries, harbours, coast defences, and so forth. We could scarcely expect anything very sound, or very profound, from such a source; and the pamphlet before us shows that if we had expected it, we should have been disappointed. With Mr. Calver the case is wholly different. He is by profession an hydrographer, and has for many years been the Admiralty Surveyor on the East Coast of England. His work answers to our knowledge of him.

Proceedings of Societies.

ROYAL AGRICULTURAL OF ENGLAND.

July 6.—Monthly Council; the Duke of Marlborough, President, in the chair. New members were elected. The usual monthly report of the Finance Committee was received. The thanks of the Council were voted to the Finance Committee for their past services.

Mr. Thompson, Chairman of the Journal Committee, reported:—

1. That in class III., Essay on Steam Cultivation, the prize of £25 is awarded to the Essay bearing the motto “Faint but pursuing,” and on the seal being broken Mr. J. Algernon Clarke, of Long Sutton, was declared the author.
2. That in class VII. none of the Essays are considered worthy of the prize.
3. The following list of the subjects for prize Essays for 1860 is recommended to the Council:—

	£	s.	d.
I. Agriculture of Berkshire	50	0	0
II. On the best period of the rotation, and the best time for applying the manure of the farm	20	0	0
III. Alterations advisable in farm management, in land of different qualities, by low price of grain and high price of meat	10	0	0
IV. Late improvements in dairy practice	10	0	0
V. Proper office of straw in a farm	10	0	0

VI. Amount of capital required for the profitable occupation of a farm ... 10 0 0

VII. On the condition of seed-bed best suited to the various agricultural crops ... 10 0 0

VIII. On the adulteration of agricultural seeds ... 10 0 0

IX. Any other agricultural subject ... 10 0 0

4. The reprint of Dr. Lang’s prize Essay on Potatoes is now laid on the table, and recommended to be sold at the following prices:—

1d. each, or 6s. per 100 to Members of the Society. 1½d. each, or 9s. per 100 to Non-Members.

Lord Leigh, chairman of the General Warwick Committee, presented the report of the Committee in reference to details connected with the Warwick meeting. Mr. Pain was elected one of the Stewards of Show-yard receipts in place of Lord Portman, who will be unable to attend.

Various communications were laid before the Council, and it was decided what replies should be given thereto by the Hon. Secretary.

Our Weekly Gossip.

THE civil service estimates for the year ending March 31st, 1860, are now in the hands of Parliament and the public in a printed form; and they certainly furnish information interesting to the latter who have “to pay,” if not to the former who voted, the prescribed amount. Taking the estimate for the Royal Mint, we find that it presents a rather favourable aspect as compared with that for the last financial year, and a marked improvement in comparison with those of former years. Last year the amount required to defray the expenditure of the Mint, including coinage, was £36,630; this year it is £35,052 5s. 3d.; giving thus a reduction of £1,588 14s. 9d. Sundry variations in the details of the two estimates go to account for this difference. For instance, last year, under the head of “extraordinary expenses,” were the charges for a new forty-horse power steam engine, a pair of rolls, &c., amounting to £2,746. This year “extraordinary expenses” are set down at nil. The loss, too, on silver coin withdrawn from circulation for recoinage, which in 1858-9 amounted to the average £10,000, this year sinks to £9,600. There is a saving, too, in the item of wages of artificers in the die department, caused by a diminution in their numbers to one half, of £512 2s. 4d.; whilst as regards the same class of workmen in the coining department, a reduction is shown to the extent of one man, and £41 12s. wages. Then, as set-offs to these prunings down, come items of additional expenditure in the shape of £5,000 for the expenses of silver coinage against £3,000 for the previous year; the ever-growing salaries of certain privileged officers, and other more trifling matters, leaving in the end the aggregate saving as shown above. The expenses for coining gold and copper are put down at the same sum for both years, namely, £8,866 and £1,500 respectively.

From the Annual Report of the Society of Arts we gather interesting intelligence respecting the operations of the several committees appointed by that Society in furtherance of scientific and artistic objects. The Gutta Percha committee has met several times, and is carrying out systematically its experiments. The Committee have had under their consideration the properties of the substance called “Pauchontee,” an Indian gum, alluded to in the Council’s report of last year as the produce of a tree of the same genus as that from which the true gutta-percha is produced. This substance has been carefully analysed and experimented upon, and a report as to its nature and properties has been sent, as requested, to the Indian Government. For this report, and the experiments and analyses, the Society are indebted to Mr. Dugald Campbell, one of the members of the Committee. From this report it appears that at the ordinary temperature it is hard and brittle, but upon the addition of heat, such as that caused by friction in a mortar, it becomes sticky and viscid, and when once this condition is reached, it does not after the lapse of several days assume its original consistence. When boiled with water, it becomes of a reddish brown colour, rendering the water turbid and slightly saponaceous. Experiments were made with a view to compare the properties of the gum with those of gutta-percha. For this purpose, the comportment of each, when brought into contact with various chemical re-agents in similar conditions, was particularly noticed, and the results are shown in a table accompanying the report. With some of the re-agents, the behaviour of the gum is precisely similar to that of the gutta-percha, while with others only a slight similarity is to be observed. Both seem to be nearly

soluble in fuming nitric acid, while ordinary nitric acid and dilute nitric acid produce a similar re-action on both. In no one case can there be said to be a decided difference. Further experiments were made by dissolving similar quantities of gutta-percha and gum in equal portions of naphtha and turpentine respectively, and after pouring the solutions from the sediment, allowing them to evaporate at the ordinary temperature of the atmosphere. After standing to evaporate the solvent, the gutta-percha in each case had returned to its original condition, while the gum was soft and sticky, except when submitted to a considerable degree of cold, when it became brittle and friable as at first. From these results it will be seen that the gum alone could not be used for similar purposes to which gutta-percha is applied. Experiments were made in order to ascertain how far the gum could be mixed with gutta-percha without interfering to any great extent with the properties of the latter, and mixtures were made containing 5, 10, 20, 30, 40, 50, 60, and 70 per cent. of the gum and gutta-percha. From an examination of these mixtures it would appear that from 20 to 30 per cent. of the gum may be added to the gutta-percha without any material difference being noticed in the mixture to the gutta-percha alone. But it is necessary to observe, that these mixtures have not been put to the test of sunlight, air, &c., which are known to decay gutta-percha more or less, according to the nature of the gutta-percha (gutta-percha not being a perfectly definite substance) and the time it may be exposed, as their application may have to extend over some years before a result could be obtained of any value.

The Surgical Instrument Committee, which had just been appointed and organised at the time of the last report, has commenced its labours; and its various Sub-Committees, into which it has been divided, have prepared a complete catalogue of the instruments and apparatus employed for the investigation and treatment of disease. This list, drawn up under the direction of the several Sub-Committees, awaits now the formal sanction of the General Committee previous to its being published. Such a catalogue has long been wanting in the profession.

The Artistic Copyright Committee of last year having made its report, embodying the principles upon which an amendment of the law of copyright in works of art should be based, as likely to meet the requirements of the public on the one hand and of the artist on the other, it became the duty of the Council at once to endeavour to procure the passing of an Act of Parliament to secure such an amended law of copyright. With that view a small Committee, as an executive, over which Sir Charles Eastlake, P.R.A., consented to preside, was appointed, and numerous meetings having been held, a Bill was settled which it was hoped would have been before the Legislature during this Session of Parliament, but the unexpected dissolution of Parliament, and the consequent interruption of business, has prevented the subject from being investigated at present. The Council, however, will still use their best exertions to bring the matter before Parliament at the earliest time possible.

The Council of the same Society have had under their consideration the best means of rendering the action of the Society available for obtaining and diffusing among the public of this country information in reference to the productions, resources, and capabilities of the Colonies, and with that view a Committee was appointed early in the session to take charge of the subject. That Committee commenced its labours by seeking and obtaining the aid of the Secretary of State for the Colonies to enable the Society more fully to carry out its object. Sir Edward Bulwer Lytton at once consented to give such official assistance as might be required, and, at the request of the Council, called the attention of the Governors of our Colonies to the wishes and objects of the Society as expressed in a letter addressed to Lord Carnarvon, the Under Secretary, in which the Council state that the best measures for obtaining the object in view would be—1. That such Colonies as consider that the meetings and proceedings of the Society of Arts would at all serve to give publicity to their resources, and tend to increase the demand for their productions, should select some competent person, or existing Society in the Colony, to frame a complete statement of the points upon which it is considered that the public of the mother-country are not sufficiently informed. 2. That the individual or public body thus selected should at once be put in direct communication with the Society of Arts. 3. That the person or persons thus chosen should also designate, and obtain the consent of, some well-informed person in this country, either himself to read, at an evening meeting of the Society, the paper prepared in the colony, or to confer with the Council as to the best method of securing

their common objects. Further proceedings may be later indicated, or may arise from the steps proposed. Should any Colony consider that a different course of proceeding would better suit the peculiar circumstances of that Colony, the Society of Arts will be quite prepared to receive such suggestions. The result has been that several of the Colonies are already in communication with the Society, and more will, no doubt, be added to the list before the Society resumes its meetings in November next, or when a sufficient time has elapsed for replies to be received.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgement:—

STEAM ENGINES, &c., 2742.

BOILERS AND THEIR FURNACES, 2720, 2731, 2744.

ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 2725, 2736, 2747, 2751, 2759.

SHIPS AND BOATS, including their fittings, 2721, 2752.

CULTIVATION OF THE SOIL, including agricultural and horticultural implements and machines, 2734, 2748.

FOOD AND BEVERAGES, including apparatus for preparing food for men and animals, 2755.

FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 2727, 2741.

BUILDINGS AND BUILDING MATERIALS, including sewers, drain-pipes, brick and tile machines, &c., 2746, 2769.

LIGHTING, HEATING, AND VENTILATING, 2739, 2740, 2764, 2768.

FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 2724, 2730, 2755, 2745, 2760, 2763, 2766.

METALS, including apparatus for their manufacture. *None.*

CHEMISTRY AND PHOTOGRAPHY, 2753, 2761.

ELECTRICAL APPARATUS, 2732.

WARFARE, 2762.

LETTER PRESS PRINTING &c., 2767.

MISCELLANEOUS, 2722, 2723, 2736, 2728, 2733, 2737, 2738, 2745, 2749, 2750, 2754, 2758, 2757, 2758, 2765, 2770.

2721. J. GRESHAM. *Improvements in apparatus for preserving ships' papers, and other papers and writings, in case of the loss of, or accident to a ship whilst at sea.* Dated November 29, 1858.

This consists in a buoy so constructed as not to sink in the event of its becoming water-logged, and to this end it is lined with cork between the cylinder and outside case. To distinguish it from other floating bodies it has raised conspicuously upon its surface a silvered globe. *Patent completed.*

2722. G. J. BENKIN. *Improvements in cleansing or purifying animal charcoal after it has been employed by sugar refiners.* Dated November 29, 1858.

Here the charcoal is placed in a vessel within which is a perforated false bottom; the charcoal is laid on this false bottom in a layer of uniform thickness, and the liquid with which the washing is to be performed is run on to the surface of the charcoal. A partial vacuum is then produced by pumps or otherwise in the space between the bottom of the vessel and the under surface of the false bottom, and this causes the washing liquid to pass respectively through the layer of charcoal, which is thus cleansed. In a similar manner air may be drawn through the charcoal and steam may be blown through it by leading steam by a pipe into the space between the bottoms of the vessel. The charcoal may be afterwards revived by burning. *Patent abandoned.*

2723. D. EVANS and G. JONES. *Improvements in air pumps and water gauges.* Dated November 29, 1858.

Here a cylinder or barrel is used having three ports one near each end, and one in the middle of its length; within this barrel or cylinder two solid pistons are used which are fixed to the ends of their respective piston rods, one of which piston rods is hollow to admit of the outer piston rod sliding or working through it. These piston rods are worked by cranks so that the pistons alternately come towards and recede from each other. When they are coming towards each other the fluid between them is driven out at the middle part or opening, when they are receding from each other the fluid is driven out through the two end ports or openings, the middle part and the end parts alternately acting as induction and eduction ways. On the exterior of the cylinder or barrel is a valve box within which a slide valve is used capable of opening a way between the two end passages or ports and the main eduction way of the pump when the middle passages or part is acting as an induction way, and also capable of opening a way between the main outlet way of the pumps and the middle part or passages when the two end parts are acting as induction ways. The fluid is received into the valve box from whence it passes into the barrel of the pump, and is thence forced into the main outlet of the pump. When constructing a pump with two barrels, as described,

it is preferred to use only one valve box and one slide valve for the two cylinders. *Patent completed.*

2724. J. LUIS. *A watch simplified with anchor escapements and rack, forming a double leever, catching in the pinion of its balance wheel.* (A communication.) Dated November 30, 1858.

The mounting of this watch is composed of a pallet plate on which is fastened the whole machinery of the watch, and on the surface the ordinary dial work of a watch is placed. The stop is fixed on the axle of the winding-up wheel as well as the dial. On the face is placed the machinery of the watch. The pallet plate forms the principal part of the box, and it is furnished with two hinges to receive the back of the box and the rim of the glass. A tall piece, with its eye or ring, is added to the pieces above mentioned. A hollow part in the pallet plate receives the spring and serves as an immovable barrel arbor; a wheel placed beneath turns of itself; to the middle of this wheel a spring ratchet wheel is fixed by a round axle passing throughout it, and turning at soft friction. When the watch is wound up in the core hole, round which the spring winds, the two pieces being adjusted together, the ratchet wheel catches in its wheel, and presents the opening where the key is placed to wind up the watch on the side of the dial. The watch can be made to wind up at the back if desired. *Patent abandoned.*

2725. J. LUIS. *A new railroad with continued supports splintered together without any wood being used.* (A communication.) Dated November 30, 1858.

This consists in replacing wood by iron in the construction of railroads. It has for principle the direct support of the rail on the ballast in its whole length, and to give it the necessary stability by adding to the bar an auxiliary surface so as to obtain the same size of surface for support as in the road having cross beams. This auxiliary surface is not manufactured in one single piece with the rail, but at the time of placing the rails it is bound with it by hooks and belts of iron. *Patent abandoned.*

2726. A. A. BURTON. *A moveable face and handle for smoothing irons.* Dated November 30, 1858.

Here the stone is a hollow box similar in form to the smoothing iron, open at the top, having a toe or front covering piece to hold the iron in it, and at the other extremity a loose swing handle which doubles over the smoothing iron handle. *Patent abandoned.*

2727. A. MARKS. *Improvements in the manufacture of braided articles.* Dated November 30, 1858.

This consists in causing a core of wood (or other material which is too rigid to permit of its being wound on reels and passed over pulleys) to travel while the braiding threads are being laid on it, so as to allow the work to be produced at all times at or very near one point, whatever be the length of core employed. The core is placed in a tube passing through the centre of the table, and rising above it nearly to the point where the braid is formed, and as the braid is produced the core is drawn up out of the tube by a cord passing over a pulley placed over the centre of the table, at a distance above it greater than that of the largest core to be covered. This cord passes to a take-up motion, and the tube serves as a guide to the core to keep it central while the core is being drawn up. When the core is not sufficiently stiff to remain straight in its length while it is being braided upon, it is kept straight by being held in a state of tension by a weight or spring. *Patent abandoned.*

2728. D. THOMPSON. *Improvements in machinery for raising water and other liquids.* Dated Nov. 30, 1858.

The inventor constructs a wheel similar to an overshot water wheel, but with each bucket covered throughout the greater part of its length, leaving only a mouth open for the entrance and exit of the water. These buckets descend into the water as the wheel revolves, and come up full of water or nearly so. At the upper part of the wheel the water is discharged into a trough which is placed to receive it. Holes or passages may be made for ventilating the buckets or allowing the air to escape and enter as the water flows in and out. The wheel may be made to discharge at the circumference, or at the side, or at both sides, as may be desired. When variations occur in the level of the liquid to be raised the wheel is mounted on a shaft which can be raised and lowered while still remaining in gear with the driving pinion, &c., and the receiving trough may also be raised and lowered when required. *Patent abandoned.*

2729. J. THOM and T. M. HALL. *Preventing the fusion of fire-bars in locomotive or other furnaces.* Dated Nov. 30, 1858.

This consists in placing a small pipe running transversely under the heel of the fire-bars. In this pipe holes are to be drilled, one opposite to each space between the bars. On turning a cock with which this pipe is furnished, a jet of water will be thrown between the bars along their whole length, and the effect will be that the bars will be kept at a comparatively low temperature, and thus their fusion and all adherence thereto will be prevented. *Patent completed.*

2730. A. E. C. SCHRIJFL. *Improvements in fastenings for belts, braces, garters, boots, porte-monnaies, portfolios, pocket-books, invoices, writing and cigar cases, reticules, bags, and other similar articles or purposes.* (A communication.) Dated Nov. 30, 1858.

On one side of a belt, porte-monnaie, &c., is fitted a clip, clasp, small case or recess, slotted, or with an opening in each side, or a double plate so connected as to have a groove on each side forming a shoulder piece, and on the end flap or other part of the belt, &c., is attached a frame or loop formed with cheeks, feathers, or tongues, or cut away at the inner sides so as to leave parts projecting inwards, which by moving the frame or loop, are caused to enter or slide into the slots or grooves in the holding piece to fasten the belt, &c., and are drawn out of such slots or grooves to unfasten it. There are modifications included. *Patent completed.*

2731. G. BOCCHETTI. *Improvements in the construction of furnaces.* Dated Nov. 30, 1858.

The inventor provides the furnace with lateral flues

running parallel with the fire-place through which he conducts air to the back thereof, and the ends of these flues he closes with copper plates pierced with fine holes which form the communication between the air flues and the fire-place. The gases of combustion pass off by a central flue, which is bent round to take the circuit of the fire place, and is brought into close proximity with the lateral air-flues. The air will thus be heated both by the direct heat of the fire-place, and also from the winding smoke-flue. *Patent abandoned.*

2732. W. E. NEWTON. *Improvements in telegraphing and in telegraphic apparatus.* (A communication.) Dated Nov. 30, 1858.

The object here is to produce an arrangement that shall not be susceptible to the changes of the weather, and that shall generate an amount of inductive electricity that shall answer all demands. The apparatus consists of an ordinary galvanic battery, using either one or more acids, a large inductive apparatus or coil, on Ritchie's or Ruhmkorff's principle, and a simple arrangement for recording the signals. This arrangement consists of two metallic points approaching but not meeting each other on opposite sides of a strip of paper on which the signals are to be recorded. The paper is to be divided into two equal spaces by lines, and to be moved between the metallic points by clockwork, so geared as to move the paper forward the distance of one space at each beat or tick of the clock, and no more, and a single wire, either insulated or not, to convey the electricity. *Patent abandoned.*

2733. J. COLVIER. *Improvements in machinery and apparatus for cutting and shaping staves and other parts of casks.* Dated Nov. 30, 1858.

This relates, first, to that part of stove-cutting called backing and hollowing. The blank to form the stave is fixed in a holder, so that it shall remain stationary during the backing, and that part of the wood intended for the outside of the cask is presented to a cutting tool so shaped as to give the required convexity to the back of the stave. The cutter travels along the stationary stave in a horizontal line, and is made to approach nearer to and recede from the stave to take off more or less wood as is necessary to give the bulge to the stave, by a guide rod or bar, the outer end of which is made to travel over a template. Thus by varying the template the travelling cutter will cut the back of the stave to any bulge required. The hollowing of the stave is effected by the same machinery, the cutter being formed convex in lieu of concave. By using the same template all the staves will be backed to the same bulge. An arrangement of levers or springs ensures the same amount of tension on the belt which causes the cutter to rotate at every part of its travel. The holder for presenting the staves in the cutter has four arms radiating from a shaft or boss, and is provided with stops for retaining that arm, carrying the stave next to be cut exactly opposite the cutters. As soon as one stave is cut the holder is moved a quarter of a turn and a fresh stave is presented, and so on, whereby a continuous feed is maintained. *Patent completed.*

2734. J. CORLSON. *Improvements in threshing and dressing machines.* Dated Nov. 30, 1858.

This consists, 1, in forming the springs or bars by which the shoes, riddles, and shag-boards of the shifting or riddling apparatus of threshing and dressing machines are suspended thicker at the ends than at the middle. The said springs or bars may be of wood or steel. 2, in forming the beating surfaces of the beaters of threshing machines of a half-octagon form in section, three of the sides having oblique ridges or projections placed in opposite directions. *Patent completed.*

2735. A. STERNBERG. *Improvements in the manufacture of cravats, braces, belts, and waistbands.* Dated Dec. 1, 1858.

This consists in manufacturing these articles in a braided form. They are made of silk, cotton, &c., in an ordinary braiding machine. *Patent abandoned.*

2736. R. H. BOW. *Improvements in railway chairs and fastenings.* Dated Dec. 1, 1858.

This relates to an arrangement of railway chairs wherein the rail is held by three dead or fixed resting surfaces, the retaining pressure upon which is brought into play by a fourth pressure arising from the action of a binding wedge or key, or otherwise. The three dead pressures are those of the pressure of the bottom of the rail upon the sole of the chair, the centre of the well of the rail against the top of the inner and lower jaw of the chair, and finally the pressure of the outer side of the upper flange of the rail against the outer and higher jaw of the chair. These three pressures are brought into action by the pressure of a key of circular or other transverse section fitting into and pressing against a corresponding concavity in the interior of the higher jaw of the chair on one side, and on the other against the outer side of the rail at the point where the lower side of the web joins the bottom flange. When the key or other binding and adjusting agent is driven into its place the pressure exerted by it binds the rail against the three resting surfaces of the chair and holds it tight. The chairs themselves generally resemble the common form, but the inner jaw is only about half the height of the outer one, and the latter is formed with a shallow concavity running horizontally along its central position. *Patent completed.*

2737. J. LOACH and J. COX. *Certain improvements in ornamenting the surfaces of japanned goods, and which said improvements are also applicable to the ornamenting of certain other surfaces.* Dated December 1, 1858.

This consists in forming ornaments from scraps of perforated zinc or other metal placed together so as to form the ornament desired whether on a round, curved, or flat surface. Over this the inventors lay on black japan or other coloured paint so as to imbed such metal ornament. After drying the whole is rubbed down and polished, when the metallic ornament will be defined by the contrast of its bright surface with the ground on which it is inlaid. In this state they paint certain parts of the metallic ornaments with transparent colours. *Patent abandoned.*

2738. E. JONES. *An improvement or improvements in the manufacture of coke in ovens.* Dated Dec. 1, 1858.

This consists in introducing air heated by the waste heat of the oven into the said oven during the process of cooking. *Patent completed.*

2739. T. P. PURSLOVE. *An improved pressure gauge for steam, gas, or other fluids.* Dated Dec. 1, 1858.

This consists principally in the arrangement of a series of pairs of tubes, each tube forming in itself a mercury gauge similar to the one commonly known as such. *Patent completed.*

2740. R. LAMING. *Implements in purifying gas, and in turning sulphuretted hydrogen, carbonic acid, and ammonia, or their compounds to profitable account.* Dated Dec. 1, 1858.

The details of this invention are too voluminous for our pages. *Patent completed.*

2741. C. F. VASSEKOR. *An apparatus for printing with different colours thread to be applied to the manufacture of textile fabrics.* (A communication.) Dated Dec. 1, 1858.

The threads are rolled upon bobbins, and a certain number of bobbins is placed upon a bobbin holder, from which the threads pass through a comb divided according to the number of threads to be coloured at the same time. Immediately behind the comb are fixed two rollers which press upon the threads and conduct them between two cylinders, one of which, the printing cylinder, bears the design to be reproduced, and the other serves as a printing table. This last-mentioned roller receives its motion by a pinion mounted upon the shaft of the main pulley of the machine, and communicates it to the printing cylinder, which in its turn transmits it to two rollers which feed the cylinders with colour. After leaving the cylinders the threads are conducted upon a reel, the motion of which is regulated according to the speed of the machine. *Patent abandoned.*

2742. J. SAMUEL and J. NICHOLSON. *Improvements in, and in connection with, marine and other steam-engines.* Dated Dec. 1, 1858.

This was described and illustrated in No. 28, at page 25, of *MECHANICS' MAGAZINE* (New Series.) *Patent completed.*

2743. E. VINRY. *An improvement in the construction of portmanteaus, desks, dressing-cases, despatch boxes, and other like articles.* Dated Dec. 1, 1858.

This consists in constructing portmanteaus, desks, dressing cases, &c., each with an envelope case or cover flexible throughout, or in part only, which cover slides in grooves at the sides or ends of the article, and either wholly or partially encloses the contents thereof. *Patent completed.*

2744. H. ADCOCK. *Improvements in furnaces and apparatus for annealing wire.* Dated Dec. 1, 1858.

Here the annealing pot or vessel is set in the centre of the furnace, and is partly protected by a casing of brick-work at its lower parts, but in place of having only one fire-grate, by preference three are constructed at equal distances apart, so as to apply heat more uniformly around the pot or vessel, the inner ends of the firegrates surrounding, or nearly surrounding, the pot or vessel. *Patent completed.*

2745. F. WARNER, J. DREYSHIRE, and A. MANN. *An improvement in the manufacture of cocks or taps.* Dated Dec. 1, 1858.

Here a valve is suspended to or formed on the end of a tube of india-rubber. The other end of the tube is flanged so as to attach it to the body of the cock or tap. The spindle or screw by which the valve is pressed on its seat passes into the tube, which is shorter than the distance between the valve seat and point of connection of the flange of the tube, so that the tube will require to be extended in length to close the valve, and the tube will when released aid in lifting the valve from its seat. *Patent completed.*

2746. G. W. BATES. *Improvements in apparatus for retaining doors, sashes, or frames, when shut or closed.* Dated Dec. 1, 1858.

Here a plate is fixed to the edge of a door-sash or frame, or to the post or frame against or in which the same is shut or closed. Through this plate a hole is formed to admit of a portion of a sphere protruding through. The sphere or such-like bolt is contained within a tube or chamber at the back of the plate, which chamber is closed at its end, and between the end of the chamber and the back of the sphere a spring is applied, which constantly presses the sphere outwards on the door-sash, or frame; or on the post or frame against which the same closes is another plate, having a hole to receive the protruding part of the sphere. By this arrangement the sphere has not only the capability of rotating, but also of receding, by which the door, sash, &c., may be opened and closed simply by pressure, and without otherwise acting on the sphere which acts as the bolt or retaining instrument. Provision may be made for fastening the sphere or bolt when shut and thus prevent it acting till unfastened. *Patent completed.*

2747. H. BESSEMER. *Improvements in railway and other wheels and wheel tyres.* Dated Dec. 1, 1858.

This consists, 1, in the use in one wheel or tyre of two or more kinds of iron, or of two or more qualities of steel, or the employment or combination of iron and steel of any desired kind or quality in the formation of a wheel, or wheel tyre, by the process of founding. 2, in the use of molten iron of any desired kind, or of molten steel of any suitable quality, or of iron and steel with other iron or steel in a heated and wrought or unwrought state in the manufacture or founding of wheels and tyres by centrifugal apparatus. *Patent abandoned.*

2748. S. NEWINGTON. *Improvements in agricultural implements.* Dated Dec. 1, 1858.

This invention is not described apart from the drawings. *Patent completed.*

2749. A. E. DAVIS and R. WRIGHT. *Improvements in the manufacture of colouring matter for spirits and other liquids.* Dated Dec. 1, 1858.

This relates to the manufacture of colouring matter from certain farinaceous substances, and from sugar or syrups made from the same. The materials are wheat, barley, sago, rice, or maize. *Patent abandoned.*

2750. F. FINCHAM. *Improvements in the construction of annealing kilns or ovens.* Dated Dec. 1, 1858.

This consists in a mode of conveying cool air through pipes of earthenware, stoneware, &c., the ends of each two adjoining lengths being brought together within a length of larger pipe of the same shape or form, so as to allow for any contraction or expansion of the inner pipes, but at the same time to prevent the sand or material used from running into the pipe. These pipes are to be so arranged under the whole bottom or sole of the kiln and embedded in the sand or other material (under the open brickwork) as to allow the external air to pass through them freely when required, the ends of the pipes by which the air is admitted being furnished with slides or shutters to regulate the admission of the air, and the other ends opening into a shaft or chimney. *Patent completed.*

2751. L. BISSELL. *Improvements in trucks for locomotive engines.* Dated December 1, 1858.

This relates to a former patent dated the 5th of May, 1857, and consists in the use of a rigid truck frame, moving on a fixed centre, that is, located between the centre of the driving wheels and the truck wheels; this frame carries the journal boxes of the truck wheels, and sustains the forward end of the locomotive on double inclined bearing blocks resting on double inclined bearings on the truck frame. Thus two truck wheels can be used, in consequence of the fixed centre where the truck frame is attached to the boiler becoming a bearing point to steady and sustain the two truck wheels. *Patent completed.*

2752. J. LEWIS. *Improvements in means for attaching sails to the yards of ships or vessels.* Dated December 1, 1858.

This invention is not described apart from the drawings. *Patent completed.*

2753. E. L. BEXKON. *The manufacture of useful alloys of aluminium.* (A communication.) Dated December 1, 1858.

The object here is the manufacture of useful alloys of aluminium by the decomposition of alumina, or the oxide of aluminium by means of carbon in the presence of, and in intimate contact with certain metals electro positive to aluminium (such, for instance, as copper, or iron, or their oxides), so as to cause the aluminium to combine with the electro positive metal and form an alloy. *Patent completed.*

2754. L. MACKIRDY. *Improved combined bathing, washing, and water closet apparatus.* Dated December 2, 1858.

This consists in combining a foot bath, body or sitting bath, shower bath, washing basin, and water-closet in one apparatus. *Patent completed.*

2755. L. MACKIRDY. *Improvements in the manufacture of sugar.* Dated December 2, 1858.

Here frames are used to receive the moulds, and these frames are either themselves mounted upon wheels, or have wheeled carriages provided to receive them, so that the moulds can with facility be brought to the heater: to be filled, and removed to any convenient situation for drainage. Arrangements are also made to place the mould frames or carriages at a level or near the heaters, sufficiently low to admit of the liquid being directly run into the moulds by taps or spouts, and the discharge of each heater may be effected through two or more branchpipes or spouts arranged to fill two or more moulds at once. Thus if there are two moulds in each row in a frame the heater may be provided with the discharge branches, so that both moulds of each row may be filled simultaneously. The mould frames have printed studs or spikes upon which the apex apertures of the moulds are entered, and which studs thus serve to close the said apertures whilst the sugar remains liquid. When the time arrives for draining the sugar each mould is lifted off its stud or studs, and its apex is inserted in an aperture or socket, and the liquid drains off into a pan fitted into the bottom of the frame or carriage. *Patent completed.*

2756. J. ROGERS. *Improvements in the manufacture of ropes, cables, cords, and lines.* Dated December 2, 1858.

For electrical purposes, this consists in laying together longitudinally plaited or braided bands, or twisted cords or lines of hemp, flax, jute, cotton, silk, &c., around a core of wires, and binding the whole together by hitching, sewing, whipping, or plaiting over with wire, thread, cotton, silk, or other suitable material, and saturating the same with a composition composed of boiled oil, rosin, patent driers, tallow, and pitch, tar, or dissolved india-rubber. These ingredients are mixed and boiled together. The mixture may be applied either in a hot or cold state. For other than electrical purposes a core of yarns, &c., is used. *Patent abandoned.*

2757. W. ROBERTSON and J. G. ORCHAR. *Improvements in machinery or apparatus for winding yarns or threads.* Dated December 2, 1858.

This relates, under one modification, to varying the spindle's rate through the frictional contact action of the circumferential edges of the frictional driving pulleys, with the lower frictional faces of the pulleys on the spindles. It also relates to a previous patent of the patentees dated 27th February, 1857, and consists in disposing the winding bobbin lower down on the spindle, and in an arrangement for gaining room for more spindles. *Patent completed.*

2758. J. TYSEN. *Improvements in obtaining and applying motive power.* Dated December 2, 1858.

This consists in obtaining and applying motive power by compressed air and water combined and made to act upon a wheel enclosed in a case to prevent the water escaping before it has produced its effect. The compression of the air and water is effected in an air-tight vessel by the aid of force pumps or otherwise. In cases where the motive power thus obtained is not sufficient to work the pumps, a supplementary steam boiler and donkey engine are combined with the apparatus for that purpose. *Patent abandoned.*

2759. J. BAILLIE. *Improvements in the construction of railway wheels.* Dated December 2, 1858.

The object here is to make a wheel avoiding all the objections and defects of the chilled cast iron wheels cast in one piece, as well as those made against wrought iron or

steel tyres, and to secure the advantages of the hard and durable chilled surface at the tread or periphery of the wheel, while at the same time the dangerous character of the chilled cast iron wheels (cast in one piece) is avoided. The invention is not described apart from the drawings. *Patent completed.*

2760. G. BRILLER. *Improvements in knapsacks for military and other purposes.* Dated December 2, 1858.

Here on the under side and near the centre between the front and back of the knapsack are placed two movable supporters, formed of metal or other suitable material, the same working upon joints, at their inner ends being provided with holes which take into eyes at the ends of the slings. The slings can be lengthened or shortened so that the knapsack can be raised or lowered by the wearer without in any way confining the arms. A pocket is also formed at the back of the knapsack opening with a flap at the bottom for placing in the great coat. The knapsack is of an oblong form, and worn in an upright position. *Patent completed.*

2761. M. HENRY. *Improvements in manufacturing and reactivating bone black or animal charcoal, and in kilns and apparatus employed therein.* (A communication.) Dated December 2, 1858.

For receiving bones to be carbonized or bone black to be restored, receivers are employed raised upon feet and fitted upon escape valves. The kiln in which the receivers are placed has a fire place at each corner of the sole, and is so constructed and provided with passages for the flames and products of combustion so that they may completely surround the receivers, and thoroughly heat them and their contents. *Patent completed.*

2762. T. BAILLY. *A mechanical movement applicable to loading fire-arms and other purposes.* Dated Dec. 3, 1858.

This consists in the adaptation and application of a toothed wheel or pinion on a travelling centre working between guides, and also working between and in gear with a pair of racks, one of which is stationary, the centre of the wheel changing its position or travelling in the same plane with the guides as the wheel works in the teeth of the racks, such centre not being fixed as usual. *Patent completed.*

2763. M. TOOK. *Improvements in apparatus for measuring the human figure, and applying the same for tracing out garments for the human figure.* Dated Dec. 3, 1858.

This consists in the use of certain metal bands for encircling the body, in combination with suitable tapes, measures, and indexes, together with other arrangements. *Patent abandoned.*

2764. G. E. NOON. *Certain improvements in machinery for generating gas from coal.* Dated December 3, 1858.

This consists, 1, in the application of a cylindrical back to kitchen ranges, &c. 2, in a kind of semi-circular cylinder called a feeder with perforated moveable front to be charged with coal for gas making. 3, in an apparatus for placing the feeders in position in cylinder back when charged with coal, and for relieving the same from coke; and also in a kind of sheet iron shield to keep dust from the gearing. 4, in a portable apparatus for purifying gas, which by a peculiar application is rendered a wet and dry purifier, combining also a mode of sealing to prevent explosion. 5, in a mode of regulating the pressure for consumption of gas, and for self-supplying the whole machine with water for cleaning &c., with the means of communicating motion to the call bell when coal is required. 6, in a peculiar construction of furnace to generate gas and steam at the same time and with the same coal. 7, in a kind of iron truck for withdrawing hot feeders from the furnace and replacing others. The invention is not described apart from the drawings. *Patent completed.*

2765. S. PETERS. *Improvements in the manufacture of pipes and tubes, and in the apparatus employed therein.* Dated December 3, 1858.

Here the sheet metal is first heated in an oven or furnace, and then passed between rollers of which the lower is grooved with grooves of different sizes, and the upper has corresponding projections, so that as the heated strip or sheet of metal is passed between the two in one or other groove according to the size of the pipe or tube to be made, it may be pressed into the form of a U. The bent sheet or strip then passes between other grooved rollers in the same machine which impart to it a tubular form. The partially formed pipe or tube is then again heated in an oven or furnace to a welding heat, and passed through a pair of grooved rollers, the grooves of one of which are larger than the corresponding grooves of the other, and the former roll is driven at a less velocity than the latter. During its passage through these welding rollers the pipe or tube is supported by a double mandril. *Patent abandoned.*

2766. E. S. JONES. *Improvements in cornets, trumpets, horns, and similar musical wind instruments.* Dated December 3, 1858.

This consists in a mode of connecting the main tube of the instruments with the small tubes for allowing the current of propelled air to pass direct from the main tube to one or other of the small tubes, and by appropriate mechanism to bring the main tube into direct communication with the side tubes, without the aid of a perforated piston. *Patent abandoned.*

2767. C. COATES. *Improvements in mandrils for printing.* Dated December 3, 1858.

Here the body of the mandril is made so that it goes easy into the copper printing roller, and is made conical at each of its ends. Over each of these conical ends a hoop of iron or steel is placed, the external diameter of which is turned to about the internal diameter of the copper roller, and its interior is made to fit the conical part of the mandril. The iron or steel hoop is also cut longitudinally in one or more places. When the mandril is put into a copper roller the hoop is forced up the conical part of the mandril, by nuts screwing on to the ends of the mandril, which expands the hoop and causes it to press against the inside of the roller, which will thus be held securely. The nuts screwing on to the ends of the mandril are made circular, and may have a

screw thread cut in their outside, on to which another nut can be screwed, so as to act as a collar to prevent the copper roller moving endways on the mandril. If the hoops are cut in more than one place so as to form two or more wedges, a pin is passed through each end of the mandril, and the ends of the pins work in recesses in the wedges. The wedges are also retained by a flexible hoop or spring which passes around them and presses them against the mandril. Thus the wedges are prevented from turning round, and also from falling off the mandril. *Patent abandoned.*

2768. C. F. VASSEBOT. *An improved apparatus for ventilating mines, or other similar purposes.* (A communication.) Dated December 3, 1858.

This consists of a cylinder formed of strong sheet zinc having an air passage attached to its side, with valves opening out from or into the cylinder according as it is to be used for ejecting and injecting air. To the one extremity of this chamber the hose or tubes are attached which convey the air from or to the cylinder. In each end or each cover of the cylinder is fixed a valve opening inwards or outwards, and which serve as the means either to expel or take in the air. The cylinder has a piston and rod which works within it, the piston having its face covered with a stuffing of india-rubber which is arranged so as to form two lips or rubbing parts, and the space in the middle being bent or compressed hollow so that there is always a pressure upon the outer edges. *Patent abandoned.*

2769. C. F. VASSEBOT. *Improved arrangements to be applied to window sashes to prevent draughts and the infiltration of water.* (A communication.) Dated Dec. 3, 1858.

Here a movable iron band is mounted upon hinges, and has at each end a spiral spring which is intended to cause the band to fall on the sill or frame when the window is opened. When the window is closed the movable band will be raised to a vertical position by two or more projections placed upon the frame of the window, and being kept in this position by the said projections it will prevent any water or draught from the outside. *Patent abandoned.*

2770. H. BEVAN. *New or improved machines for effecting or facilitating arithmetical operations.* Dated Dec. 3, 1858.

This consists of machines in which a series of figures are arranged either on the peripheries of discs, or on plane surfaces, the said discs or surfaces being capable of such changes of position as to produce under proper manipulation, and the mere process of simple addition, the product of any two numbers which it may be wished to multiply, as well as to effect or facilitate other arithmetical operations. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated June 21, 1859.

1488. G. Tomkins, of Pontymister, near Newport, Tinplate Worker. Improvements in coating metals and in the apparatus connected therewith.

1490. S. Gibbs, of Eddington, near Canterbury. Improvements in apparatus for alighting horses, mules, and other animals.

1492. J. Meikle, of Glasgow. Improvements in coating iron ships with asphalt, which improvements are also applicable to coating other surfaces.

1496. E. Oliver, of King William-st., City. Improved medicinal mixtures for the cure of rheumatism, the doloreux, lumbago, cramp, sciatica, and such like complaints.

Dated June 22, 1859.

1502. W. Goulding, of Leicester. Plough-maker. Improvements in the construction of ploughs.

1504. W. Russell, of Leicester, Ironmonger. Improvements in wheels for ploughs, cultivators, and other implements or carriages.

1506. J. Apperly, Cloth Manufacturer, and W. Cilsold, Engineer, of Duddridge. Improvements in the manufacture of wheels for carriages and engines.

Dated June 23, 1859.

1508. J. Luis, of Welbeck-st. A machine for corking bottles. A communication from J. Peury.

1509. C. F. and C. J. Varley, of Kentish-town. Improvements in proving electric conductors, and in the apparatus connected therewith.

1511. E. T. Hughes, of Chancery-lane. Improvements in the manufacture of artificial sand-stone, bricks, tiles, and similar articles. A communication from L. and E. P. de Lafarge.

1513. A. Prince, of Trafalgar-sq. Improvements in alarm locks and latches.

1514. H. Doulton, of Lambeth. Improvements in earthenware jars and bottles.

1515. A. V. Newton, of Chancery-lane. Improvements in springs for resisting sudden and continuous pressure. A communication from C. Perraton, and Messrs. J. F. Call and Co.

Dated June 24, 1859.

1516. W. Lister, jun., Master Mariner, and T. G. Garrick, Agent, of Sunderland. Improvements in ships' windlasses, and other like apparatus, applicable also to the steering of ships.

1517. J. Mills, of Heaton Norris, Machinist. Improvements in the manufacture of keys and gibs, and in the machinery employed therein.

1518. A. Cheneau, of Paris, Merchant. Improvements in paddle-wheels.

1519. W. Clark, of Chancery-lane. Improvements in sewing machines. A communication from J. S. Goodridge.

1520. G. Redrup, of Loughborough, Brewer. Machinery for the cutting of shives, bungs, corks, spiles, and vent or other pegs.

1521. R. Hornsby, jun., of Grantham. Improvements in ploughs, and in giving motion to ploughs and other agricultural implements by steam-power.

1522. P. Faure and J. Pernod, of Avignon, France. An improved process for utilizing the residues of madder in

the manufacture of garancine and other preparations of madder.

1523. J. Drury, of Exley, near Halifax, Engineer. Improvements in steam-engines and boilers.

Dated June 25, 1859.

1524. T. Howard, of King and Queen Iron Works, Rotherhithe, Engineer. Improvements in condensing steam in engines where superheated steam is used.

1525. W. J. Sluce, of Bethnal Green-road, O. Murrell, of Bethnal Green-road, and W. Hudson, of Hackney-road. An improved method of generating steam.

1526. C. W. Williams, of Liverpool. Improvements in steam-boilers.

1527. W. E. Newton, of Chancery-lane. Apparatus for exhibiting stereoscopic pictures. A communication from J. S. Perry.

1528. J. Roberts, of Upnor, Terra Cotta Manufacturer. Improvements in filters.

1529. J. Boden, of Southampton, Engineer, and W. Clark, of Southampton, Boiler Maker. Improvements in apparatus for superheating steam.

1530. R. Russell, of Sheffield, Manufacturer. Improvements in breech-loading fire-arms, and in projectiles to be used therewith.

1531. W. Coppin, of Londonderry, Marine Architect. Improvements in apparatus for raising sunken and stranded vessels and their cargoes, and for raising and lowering other bodies into, and out of, the water, parts of which improvements are applicable to raising weights generally.

Dated June 27, 1859.

1533. G. Wrigley, of Dunkinfield, Machine Maker, and T. H. Wrigley, of Moseley, Overlooker. Improvements in self-acting mules for spinning and doubling.

1534. D. J. Fleetwood, of Birmingham, Copper Agent. An improvement or improvements in shaping metals.

1535. B. Burton, of Brooklyn, U.S. Improvements in breech-loading fire-arms.

1536. G. Smith, of Orange County, U.S., Engineer. An improved contraction of primer for fire-arms.

1537. T. Leigh, of St. Mary Cray, Millwright, and J. Line, of the same place, Paper Maker. An improvement in paper-making machinery.

Dated June 28, 1859.

1540. A. V. Newton, of Chancery-lane. Improved machinery for cutting corks. A communication from E. Conroy.

PATENT APPLIED FOR WITH COMPLETE SPECIFICATION.

1561. L. L. Tower, of Massachusetts. A new and useful machine for damping and wetting paper, &c. A communication from J. A. Lynch. Dated June 30, 1859.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

(From the London Gazette, July 12, 1859.)

543. J. Templeman. Artificial fuel.

545. D. Lichtenstadt. Paper and other fabrics.

551. W. F. Dearlove. Chopping machine.

563. J. Harrison. Rotating window sashes.

573. C. F. Dennet. Bayonets.

575. J. Cowban and A. Andrews. Spinning.

576. B. A. Brooman. Boiler stays. A communication.

586. G. Leach. Reeling yarn.

598. J. P. Clarke. Reels for cotton, &c.

610. J. A. Williams. Cultivating land.

621. J. Yuill. Saddle-trees.

623. H. Lodge. Protecting ships' batteries.

643. T. Lightfoot. Fixing colours on fabrics.

653. J. Dixon and R. Clayton. Rolling iron and steel.

664. W. Avery. Screws.

665. J. Michel-Denys. Railway crossings.

733. W. Clark. Separating oats from chaff. A communication.

770. B. and C. L. Smith. Dyeing and printing.

810. F. Morton. Fences and posts.

811. W. E. Newton. Cleaning rice. A communication.

881. W. Hooper. Insulating conductors.

882. W. Hooper. India-rubber.

921. B. A. Brooman. Red dyes. A communication.

981. F. and W. Edwards. Looms.

1033. T. A. Weston. Pulley.

1060. J. Holroyd. Finishing cloths.

1335. A. Mickelthwait, J. Peace, and S. J. Hobson. Coating springs and bands.

1350. G. H. and H. R. Cottam. Stable fittings.

1372. A. V. Newton. Millstones. A communication.

1392. R. R. Fairgrieve and S. Bathgate. Winding yarns.

1394. J. and W. Henderson, T. Bagley, and S. Holdsworth. Looms.

1420. F. A. T. de Beauregard. Generating steam.

1428. A. V. Newton. Boats. A communication.

1437. A. V. Newton. Polishing wheels, &c. A communication.

1488. G. Tomkins. Coating metals.

1497. R. Smith. Looms.

1501. C. Clarini. Metal nails.

1516. W. Lister, jun., and T. G. Garrick. Ships' windlasses, steering, &c.

1520. G. Redrup. Cutting shives, bungs, &c.

1521. R. Hornsby, jun. Ploughs.

1529. J. Boden and W. Clark. Superheating steam.

1561. L. L. Tower. Wetting paper. A communication.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed July 8, 1859.

69. J. T. Forster.	126. J. Daughish.
72. E. D. Clegg.	181. J. L. Clark and J. Muirhead.
83. W. Tillie.	211. E. Musbet.
84. D. E. Hughes.	226. I. Hammond.
87. C. W. Siemens.	265. J. Lane.
88. F. Verzmann and A. Oppenheim.	278. J. P. Booth.
89. N. P. Burgh.	497. G. Turnbull.
92. W. Oliver.	1083. J. Toussaint.
103. C. Beslay.	1153. R. Fearall.
105. E. A. Lightoller.	1155. B. D. Kay.
118. T. Herbert and E. Whitaker.	1203. J. H. Johnson.

Sealed July 12, 1859.

106. W. Bennett.	122. S. Holt.
110. J. Pickaley and R. Sims.	125. W. Davis.
112. D. L. Banks.	131. D. L. Banks.
113. J. J. Stevens.	431. W. E. Newton.
114. F. J. Mancaux and E. N. Viellard.	469. J. Robinson.
115. J. Grist.	869. K. Wapenstein.
	939. E. Partridge.

PATENTS ON WHICH THE THIRD YEAR'S STAMP DUTY HAS BEEN PAID.

1578. J. Lewtas and J. Humphreys, jun.	1590. A. L. S. and E. C. A. Chenot.
1583. L. Blackstone.	1595. W. Laine.
1586. R. Shaw.	1616. W. B. Adams.
1587. A. L. S. and E. C. A. Chenot.	1622. T. Jerome.
1588. A. L. S. and E. C. A. Chenot.	1638. R. Harrington.
1589. A. L. S. and E. C. A. Chenot.	1647. W. B. Adams.
	1661. W. Watt.

LIST OF SPECIFICATIONS, &c.,

Published during the week ending July 8, 1859.

REMARKS.—The more speculative articles of Metals have been materially affected by the peace news. Scotch Fig-iron has advanced upwards of 5s. per ton. Spelter is higher by about £2 per ton. English Tin has been successively advanced £9 and £1 per ton—the whole of the quantity of Banca put up for sale by the Dutch Company having been taken at a price equal to about £143 per ton here, and the article is now firm at about £146 per ton. Copper and Lead are as yet without change.

RIFLED GUNS FOR THE NAVY.

THROUGH all the mists of doubt and perplexity which envelope the subject of our national defences one clear principle shines steadily forth for our guidance, viz., that at no time, and for no cause, must we permit any nation whatever to surpass us in the selection or production of naval and military weapons. There is no class of politicians in this country, we believe, who will for a moment question the truth of this principle, nor is there any who will deny that of the various services, the navy is that which least of all must be permitted to be inferior in any respect. Yet there are grave reasons, we regret to say, for believing that the French are silently assuming a vast superiority to us in one very important particular.

More than a month since we were privately informed, by a gentleman whose authority in all matters relating to guns, whether cannon or small arms, we have great cause to trust implicitly, that a large number of naval guns were being rapidly rifled in the French ports. This information had not long been received when the *Marseilles* correspondent of the *Times*, in visiting the arsenal at Toulon, discovered several of the rifled guns on the wharves there, and learnt that many more smooth-bore guns were undergoing the process of rifling. This intelligence he duly communicated to the public in the columns of the leading journal. More recently (on July 9th) the same gentleman, through the same channel, has afforded further information upon this important subject. He says (speaking again of Toulon) "the most noticeable feature in the Arsenal is the effort made to prepare rifled ordnance for the navy. Twelve 30-pounders had just arrived, and were waiting to be fitted with locks preparatory to being sent to the fleet. The system which appears to be definitely adopted, after repeated experiments, consists of three grooves, about three inches broad and an eighth of an inch in depth, with a twist of one-sixth. More guns of the same kind were being landed on the quays. From the exertions made to provide French men-of-war each with a certain number of rifled guns, the question naturally suggests itself whether it is prudent for English ships to wait until they can be supplied with Armstrong guns. The immense superiority of rifled ordnance may be accepted now as an established fact. Yet so enormous is the demand, that for the protection of English interests I believe many years must elapse before Armstrong guns can be supplied to all our ships, land batteries and field batteries." He further suggests that it would be a wise precaution to rifle all the smooth-bored guns of small calibre as far as possible.—"It will be a long time, I apprehend, before the 68-pounders (solid shot) are superseded, but, here is no reason why the lighter guns, 32 and 24-pounders, now supplied to ships should not be rifled."

Now, with these remarks before us it can scarcely be doubted that the French Government are really preparing to arm a fleet with rifled cannon. Not with a very efficient form of that instrument, it is true, because a mere ordinary service gun with twisted grooves formed in it can scarcely be expected to be so. But the fact to be observed is that, whatever these guns may be, we have nothing of equal efficiency to bring against them. Even if we had a good prospect of getting an early supply of Armstrong guns—which we have not—we could not forget that these are really untried weapons, and weapons which in naval warfare may scarcely be found to suit our purpose. Sailors above all men need have simple instruments to handle, and the Armstrong gun is very far from this. But whether fit for sea service or unfit, reliable or otherwise, we have no Armstrong guns at present. Nor have we any but the old-fashioned smooth-bore cannon to occupy their place. Ought this to be the case? Are we to see armaments of rifled cannon sent on board French fleets, and take no corresponding step ourselves? This we are doing now; but are we to continue thus supine? We put these questions—and we can do no more—with the earnest hope that the necessity for them may speedily cease.

ANCHORS FOR THE ROYAL NAVY.

MR. LINDSAY from his place in Parliament, Mr. Busk in his *Navies of the World*, Mr. Trotman in the *Times* and elsewhere, and many other interested and disinterested gentlemen, are just now doing their best to make us believe that the Admiralty almost deserve impeachment for not adopting the Trotman anchor in the Royal Navy. On the 8th instant, during the debate on the Navy Estimates, Mr. Lindsay informed us that nine years ago he devoted a considerable portion of his time as a member of a committee to inquire into the best description of anchors. Seven anchors were brought, he said, before the committee. They tested them in every possible way, and unanimously arrived at the decision that the Admiralty anchor was the worst of the seven. For nine years that report had been in possession of the Admiralty, and the same description of anchor still continued in use. But, more than that; for 17 anchors, from 20 cwt. to five tons weight, the Admiralty paid £3,434 17s. 6d., whereas the market price of the most eminent firms was only £1,428. "When he found the Admiralty wrong in these two items, he thought there was great reason to fear they were wrong in many others, and that they paid far too much for stores and materials. Why was it so? The answer he had received to that question in the matter of anchors was, that the Admiralty had been in the habit of dealing with a particular firm. "One firm had a monopoly—and a very nice monopoly it was for them—at the expense of the poor taxpayers." Mr. Busk, in his work before-mentioned, tells (curiously enough, considering the ostensible nature of his volume) the same tale as Mr. Lindsay, with even less moderation, introducing it as "a little piece of Admiralty jobbery," although he afterwards inconsistently "disavows all intention of imputing improper motives to the members of the different Boards of Admiralty." Mr. Trotman himself, in the *Times* of the 13th inst., almost rivals Mr. Busk in his manner of stating the case. The subject is one, therefore, which will bear a little intelligent discussion.

Now, all these gentlemen proceed upon three assumptions: first, that the committee of 1852 were appointed to finally determine by experiment the best of several existing forms of anchor; secondly, that the trials made were amply sufficient for that purpose; and, thirdly, that the Admiralty were bound to adopt throughout the naval service the anchor which the committee pronounced the best. In reference to the first of these assumptions it is necessary to remark that the committee were appointed in deference to the expressed desire of certain private shipowners and others—prompted doubtless by the owners of some of the competing anchors exhibited in the Great Exhibition of 1851—rather than in consequence of any glaring proofs of defect in the Admiralty anchor; in reference to the second assumption it is to be remarked that the committee themselves put forth their report in 1853 with manifest misgivings, carefully inviting a reconsideration of their decisions by others, and furnishing the materials requisite for the purpose; and, in reference to the third assumption, it should be observed that the Admiralty gave no promise whatever to bind themselves to act upon the decision of the committee, who were only appointed, as we have said, in consequence of requisitions urged upon the Admiralty by others.

Nor, we submit—although the Admiralty will not thank us for saying so—were the gentlemen appointed to that committee in any way competent, of themselves, to determine the question submitted to them. Who were they? Admirals Sir Montague Stopford, G.C.B., George R. Munday, and C. Hope; the Master-Attendants of Her Majesty's dockyards at Sheerness and Portsmouth—Mr. J. Aylen and Mr. J. Tonkin; also Mr. W. S. Lindsay, M.P., Mr. Duncan Dunbar, chairman of the General Shipowners' Society; Mr. Anthony Ridley, deputy chairman of the Mercantile Marine Board; and the following members of Lloyd's Committee—Messrs. William Drew, William Phillips, and George Marshall. Very good men most of these doubtless; but in the practical trials of anchors many questions of importance—questions of material, manufacture, &c.—must, or should, have been raised respecting which not one of them was in the least degree competent to pronounce an opinion. The Admiralty were doubtless themselves to blame for the defective constitution of the committee; but that consideration in no way helps us to place our confidence in the results arrived at.

It may suit the purpose of Mr. Trotman and his friends to endeavour to make the decision of this committee binding upon the Admiralty; but sensible men are not apt to deem the reports of such bodies at all times sufficient to authorise great changes. And in this particular case the Admiralty have many—we do not say sufficient—grounds for inaction. In the first place the Report of 1852 has been seriously weakened by the criticism to which it has been subjected by a practical anchor-smith—Mr. George Cotsell, the master smith of Chatham Dockyard. This gentleman, although a servant of the Admiralty, is not to be considered a partizan, for he has more than once been snubbed, and had his writings discountenanced by the Board. Despite of this, however, he has doubtless exerted a strong influence in favour of the Admiralty (or Sir William Parker) anchor, at present in use in the service, and has likewise done much in the way of discrediting the report of the committee of 1852. We cannot here recapitulate all the facts and arguments adduced by him; they can all be seen in an eighteenpenny volume, published by Mr. Weale, of Holborn.

We may remark, however, that he insists strongly upon the facts that in the trials of 1852, the Admiralty anchor tested was taken at random from a large number, while all the other competing anchors were made specially for the purpose; that the Admiralty anchor was the only one (with one exception) the shank of which did not break; and that the approximate numbers selected by the Committee to represent the relative values of strength, holding power, facility of canting, sweeping, stowing, &c., were most injudiciously selected. Thus, while fifteen marks only were given for the "strength" of the anchor, no less than eighty were given for "holding long and short scope." We do not think with Mr. Cottrell, that the highest value is due to strength; but we certainly believe that this quality is greatly undervalued by the Committee.

Having said thus much, by way of moderating the extravagance of the conclusions to which Mr. Trotman invites the world, we have now to add that he is by no means without reason for urging the gradual adoption of his anchor by the Admiralty. That anchor, although not so far superior to the Admiralty anchor as he would fain have us credit, is unquestionably an excellent instrument, and may be produced at much lower prices than are at present paid for anchors for the royal navy. We do not accept Mr. Lindsay's figures on this point without many reservations; but we do believe the adoption of the Trotman anchor would be a pecuniary advantage to the nation. Certainly Mr. Trotman can do nothing fairer (to all except himself) than he has already done in making the public challenge, which appears in his letter to the *Times*. He says: "That no doubt may exist in the mind of any one as to the motives which lead me to decline their 'lordships' offer of the 17th of March, I am willing to submit a Trotman's anchor of 50 cwt., costing £90, to be tested at my own risk and cost, against any anchor now in Her Majesty's dockyard of 100 cwt. or more, the contract value of which exceeds £365. It shall sustain a higher proof, possess greater holding power, and perform in a more efficient manner every duty required in the larger anchor, such as bringing a ship to, holding on at long or short scope of cable—in fact, that it may be subjected to the most severe test professional ingenuity can devise, in order to ascertain the relative qualities and values of the Admiralty anchor and Trotman's, the latter being half the weight and one-fourth the cost of the former." The Admiralty will be wicked and slothful stewards indeed, if they allow this challenge to pass unheeded. The public interest forbids them to do so.

We cannot conclude this article without observing how sadly poor Sir John Pakington has involved himself in this business. Mr. Trotman says:—

Sir J. Pakington took credit to himself when he stated to the House "that one of his last acts before leaving office was to offer another trial to Mr. Trotman." If, however, their Lordships were indeed serious, and desired only additional proof of superiority, there was the result of the Hon. Captain Denman's experience of more than four years with my anchor on board the Royal yacht; also the testimonies of commanding officers of the Cunard line, the Peninsular and Oriental Company, and the world-wide experience of the mercantile marine, throughout which Trotman's anchor is almost universally used. Last year Sir J. Pakington stated to the House that "he believed the fact was, Trotman's anchors had not been brought into general use on account of the great number of anchors of the old construction which were still in Her Majesty's dockyards." This year his refusal is couched in a new form, and he told the House "he knew nothing of the quality of those anchors from his own personal knowledge, but on consulting practical naval officers the reply he received was that they did not in their experience find them to

answer. He was told that Trotman's anchor, when once it could be got to hold, was a good one, but that officers could not rely on its holding." Now, Sir, I solemnly declare there is not and never has been, a single anchor of my construction used in the navy, save the one on which the Royal yacht still depends for her safety. What ground, then, has Sir John for making so grave and so injurious a mis-statement?

When will our affairs be so managed that an excellent but unfortunate Chairman of Quarter Sessions shall not be compelled to speak officially to an assembly of gentlemen upon subjects of which he is totally ignorant? Only conceive, reader, of Sir John Pakington, the representative of Droitwich, rising in the House of Commons to speak—even from hearsay—of the holding properties of Trotman's anchor! We need not wonder that his observations on such a subject fail to bear scrutiny in the columns of the *Times*. Would that some power might save us from such constitutional absurdities—not to say shams!

THE COST OF SHIPBUILDING IN THE ROYAL DOCKYARDS.

CURIOUS facts—not unfamiliar to ourselves, however—have lately been brought forward in illustration of the cost to which the nation is put for shipbuilding in the Royal Dockyards. In that speech of Mr. Lindsay's to which we have already more than once referred, we find these facts put in a connected and striking form. They will bear recapitulation here. It appears that a Return has been made of the cost of a number of ships built in our dockyards, all of the same size—1,462 tons burden. The first of these vessels—the *Satellite*—was built at Devonport, and the expenditure for shipwrights' labour was in her case said to be £6,450, or at the rate of £4 8s. 3d. per ton. The second, the *Pelorus*, was also built at Devonport, and the shipwrights' wages were £6,712. The *Scylla* was built at Sheerness, and the expenditure for the same purpose was £8,621; while in the case of the *Racoon*, built at Chatham, it was £6,321. The cost of labour in one dockyard was apparently, therefore, much greater than in another. Thus, the *Pearl*, built at Woolwich, cost us £6 18s. 5d. per ton; while the *Satellite* built at Devonport, and the *Racoon* at Chatham, cost £4 6s. 6d. per ton. There must be something radically wrong, said Mr. Lindsay, to cause such a discrepancy as this. Two frigates built in a private yard on the Tyne for the Russian Government—viz, the *Tartar* and the *Cossack*—cost £2 8s. per ton. That included not only the cost for shipwrights, but the cost of fitting them out for sea; whereas the entire cost of fitting out the *Pearl* for sea was £8 13s. 11d. It was evident, to Mr. Lindsay's mind, that there was something wrong in the management of the Royal Dockyards. "Why could the men not be employed as they were in private dockyards? If they were employed on piecework, instead of the labour account of the shipwrights being £8 13s. 11d. per ton, it would not be more than £2 12s. per ton. The rate for labour in the present estimates was £1,527,000. Of this £1,000,000 at least was for shipwrights; and on this item alone there might be a saving of £400,000, while the work would not be one whit less efficiently done."

Now, we are not about to blame Mr. Lindsay, by any means, for the part which he has taken in this matter. He is wrong, and in error; but innocently so in this case. If the facts really were as the Return itself makes them appear, his criticism would in the main be sound and pertinent. But the facts are not as they there appear. We know somewhat of the manner in which accounts are kept in the Royal Dockyards, and we unhesitatingly state that it is

not possible to get from those accounts what the Return professes to give, viz, the actual amounts of money expended for labour upon particular ships. The Surveyor of the Navy, or his staff, has acted most unwisely, in our judgment, in putting forth such a Return. We entirely deny that its accuracy can be guaranteed.

Let us glance for a moment at the circumstances operating in two neighbouring yards which are contrasted most unfavourably in this return—Sheerness and Chatham. Now, in the latter yard, where there are numerous building slips, by far the larger portion of the shipwrights are constantly engaged upon what is called "new work"—in other words, upon the building of new ships. The interferences occasioned by the pressure of fitting and repairing of ships occur but comparatively seldom. In Sheerness yard, however, the case is wholly different. There is but one small building slip in it; and the regularity of the work expended upon the single ship there building is, of necessity, seriously impaired by the frequent putting on and calling off of hands for repairing and fitting purposes. How this would tell upon the nominal expense of the ship in progress of building will be readily conceived. Like effects are produced in another and somewhat similar way. In the building of a ship upon the stocks, in order that she may be built economically, it is indispensably necessary to adjust the number of hands employed upon her to the varying state of her progress. There are times when less than 100 men, say, are all that can be kept economically at work upon her; there are other times when five times that number may be advantageously employed. Now, in a yard where there are several ships in various stages of advancement simultaneously in progress, this adjustment of hands can be properly attended to. But in a yard like Sheerness, with its one building slip, and an exceedingly fluctuating amount of fitting and repairing to be executed, it is quite impossible to economise the labour in this way. The same remarks apply, to a certain extent, to Woolwich Dockyard. These are the causes which, with others—for we are by no means attempting to treat the subject fully—tend to produce those discrepancies which, by their grossness, have struck the senses of the member for Sunderland. And these are causes, it will be observed, which cannot be removed.

It may occur to some that it would be better to build no ships at yards circumstanced like Sheerness. But this is a mistake; it would be worse. With a ship in progress on the stocks, there is a means of absorbing your spare work in times of slackness, when there is but little fitting or repairing to be done; and although its absorption in this way is undoubtedly attended by a loss, the loss would be greater did this provision not exist.

But when all due allowances are made for facts of this kind, it is useless to look for accuracy to the accounts as they are at present kept. An immense amount of Dockyard labour gets "charged," in the course of months, to wrong vessels. Nor is it, indeed, practicable to avoid this. It is sometimes as impossible to estimate the labour expended upon the building of a particular ship as it would be to measure the work done by the French battalions in the capture of each of the several positions of Solferino, Cavriana, &c., at the last great battle. The mistake lies, as we have said, in the present instance in the putting forth of the Return in question. Far better admit the difficulty than ignore it, and expose yourself to such hard and inexorable critics as Mr. Lindsay.

Mr. Lindsay's remarks upon "piecework" and the cost of shipbuilding in private dock-

yards, are open to many corrections ; but having dealt with the main question, we must defer the consideration of minor points for the present.

THE FAMILY OF HENRY CORT.

THE scandalous neglect of the Cort family, to which we have so often drawn attention, is beginning to cast a shadow even upon the Queen's Government. A second time the *Times* newspaper, in a leading article, states the facts to the public, and reproaches the nation and its representatives with ingratitude. As the pen of one of the most accomplished barristers of the metropolis—a gentleman eminently qualified by years of special study of the laws regulating property in inventions for discussing this subject—is tracing in our own columns the history of Henry Cort's improvements, we need not enter upon any minute consideration of them. The *Times*, however, in its last article states the leading facts of the case with so much simplicity that we may well repeat here what it says. Briefly, then, the facts are these :—

The family of Henry Cort claims compensation from the British nation for the unjust forfeiture of their father's rights. Henry Cort was the inventor of the process for the conversion of pig-iron into malleable iron by the flame of pit-coal in the puddling furnace. Before his time our ironmasters were compelled to employ charcoal for fuel. Having thus got pig-iron into a malleable condition, Henry Cort invented a further process for drawing it into bars by means of grooved rollers. In other words, he reduced the labour and cost of producing iron to one-twentieth of what they were before his day, and the iron was of a better quality. How, it may be asked, can the children of such a man be in want? How is it they are not among the wealthiest of the land? The answer is this :—Mr. Cort had entered into partnership with a certain Mr. Adam Jellicoe, at the time Deputy-Paymaster of the Navy. Jellicoe advanced money, and was to receive in return half the profits of the trade. Cort assigned to him, besides, his patent rights as collateral security. In the year 1789 Jellicoe died, and was found to be a public defaulter. The Navy Board issued "extents" against the trade effects of Cort and Jellicoe, and confiscated Cort's patent rights, which they treated as valueless. The hardship of the case was this,—a property which should have been estimated at the value of £250,000 was forfeited to insure payment of a debt which the estate would have satisfied seven or eight times over had it been fairly handled. Nobody but the ironmasters profited by this mismanagement, and the Cortes were ruined. "It should be emphatically re-marked," says the *Times*, "that it is not even suggested Cort had anything to do with Jellicoe's defalcations. He was purely the victim of a swindler ; but, although it might be right to cause the firm to refund the sums in which one of the partners stood indebted to the public, it was utterly wrong to destroy the noble fortune which this ingenious man had won by the force of his intelligence and industry. England is indebted for a very large share of her present prosperity to Henry Cort's inventions, but now his four surviving children—all of them being persons about seventy years of age—are beggars, and only saved from the poorhouse by pensions amounting in the aggregate to £90 per annum. There should be more gratitude in an iron age to the children of Henry Cort."

All this is what we have substantially said before, and said not altogether in vain. Still, a settlement of the claims of the family has yet to be made. It is for the Queen's ministers

now to act in the matter. They are not slow to reward men of their own class. Let us hope they will no longer delay to do simple justice to these aged persons, who, if the creation of enormous wealth gives any claim to competence, are the most conspicuous living symbols of our injustice and ingratitude. We commend the memorial now in the hands of the First Lord of the Treasury to his strong sense and liberal spirit.

[Since the above was written, Mr. W. Fairbairn has nobly offered to subscribe £100 through the editor of the *Times* towards a national subscription in favour of the Cort family. We hope his liberality will be duly imitated.]

CAPTAIN BLAKELY'S IMPROVEMENTS IN CANNON.

THE beautiful theory of great-gun construction which Captain Blakely, R.A., propounded to the world four years ago, and which has been independently conceived and embodied by the inventors of the great Mallet mortar and the Armstrong gun, has lately received strong and unexpected confirmation. Captain Blakely, in our own columns and elsewhere, has argued, in laying down the basis of his system, 1st, that any metal tube pressed on from within must stretch ; 2nd, that in stretching it must become thinner ; 3rd, that the sides of the tube becoming thinner, the outer parts, particularly of a thick tube like a gun, must be less stretched, therefore less strained, than the inner ; because, to permit of their being as much stretched, the sides would have to become absolutely thicker and the mass of material greater than at first ; 4th, that a tube in which the outer parts are less strained than the inner must be weaker than if all could be equally strained. These principles are so plain, and so manifestly true, that they can scarcely need extraneous recommendation to any mind. Major Wade, of the U.S. Ordnance, has lately, however, made numerous experiments for his Government (who have been so liberal as to publish them, together with many other researches, in a book entitled "Reports of Experiments on Metals for Cannon") which throw much light upon these four propositions. To these experiments Captain Blakely lately drew the attention of the members of the United Service Institution, in a paper* from which we derive the facts that we are about to notice.

In 1846 Major Wade, when testing some muskets by hydrostatic pressure, found the elasticity of sound barrels such that a column of water in them, 21 inches high, could be diminished half an inch by a pressure of 2,000 lbs. A column of water 39 or 40 inches high he shortened $\frac{1}{2}$ of an inch with a pressure of 2,400 lbs. When the pressure was removed the water recovered its original height nearly. This result could not have been owing to the compression of the water, which would have been imperceptible with such a slight pressure ; the musket barrels, therefore, must have increased in diameter during the strain. In 1851 Major Wade measured the change in size of some hollow cast-iron cylinders, when strained from within by hydrostatic pressure. Not only were they all enlarged during the continuance of the pressure, but in every case an addition of pressure produced an increase of diameter. He also found that each increase of strain diminished the thickness of the tube. Further, that where the sides were less than one-third of a calibre in thickness, the outer diameter was increased on an average $3\frac{1}{2}$ times less than the inner ; and that in cylinders 2, 3, and 4, where the metal was $\frac{1}{2}$ of a calibre thick,

* Published in the last No. of the *Journal of the Institution*.

the outside was stretched on an average seven times less than the inside. Thus the first three propositions of Captain Blakely were appropriately verified. Again, in October, 1844, Major Wade burst two 18-pounder cast-iron guns by hydrostatic pressure to find their strength. He afterwards carefully tested the strength of the metal to resist a direct tensile strain. One of these guns burst with a pressure of 9,000 lbs. per inch of resisting metal, yet a sample bar of the gun showed a strength of 27,350 lbs. per inch. The other burst with a strain of 6,082 lbs. per inch, whereas the sample showed a tensile force of 22,204 lbs. Here we have proof that some part of the metal did not exert its strength, and that in each of these guns at least the useless part amounted to the great proportion of more than two-thirds of the whole. In his report to the Colonel of Ordnance at Washington Major Wade wrote on the subject as follows :—"The relation between the force applied in producing a fracture in cast-iron by a tensile strain in the axis of the specimen, and by that of hydrostatic pressure within the bore, appears to be somewhat greater than as three to one." Another experiment made by Major Wade a few weeks later showed that it is the outside parts of cylinders which do not exert their strength. He turned down the outside of a 6-pounder cast-iron gun in a lathe to such an extent as to form, from the breech near to the trunnions, a cylinder of the uniform thickness of one calibre, that is to say, with a thickness of metal on every side equal to the diameter of the bore. He cut off the trunnions, and turned a second cylindrical portion in the middle of the gun with the thickness of half a calibre. In front he formed a third cylinder with metal only one quarter of a calibre thick. With a hydrostatic pressure of 12,400 lbs. per square inch, the thin part burst in four fissures. The piston was then inserted in the middle part where the metal was half a calibre thick, and a pressure of 20,000 lbs. burst it in three fissures, one of which extended 16 inches into the thick cylinder. In his report Major Wade wrote as follows :—"It appears from these results, that the power of resisting in cylinders of the same quality of iron, and of the same diameters of bore, but of different thickness, varies as the thickness, but in a less ratio. Hence the increase or the diminution of the thickness of iron in a gun does not increase or diminish the strength in like proportion." From a table which he gives we see that a 6-pounder, when only one-fourth of a calibre thick, required a pressure of 12,400 lbs. per inch of bore to burst it ; but that with double the thickness of metal, an addition of only 7,600 lbs. pressure, or about five-eighths of the former, sufficed to destroy it. The second equal thickness of metal, then, only exerted five-eighths as much power as the inner, the total strength being less than if they had been equally strained. "Although these experiments would by themselves," says Captain Blakely, "be insufficient to establish a theory, and although I was unable by reasoning, founded on pure science, to convince many persons of the soundness of my views, still I trust that the mutual corroboration of argument and experiment will have greater effect. Here, in England, an opinion is expressed, that for certain reasons, cylinders if strained would stretch, and stretch more inside than outside ; in America a number of cylinders are measured during strain, and without exception all do stretch with every increase of strain, and all do stretch more inside than outside. This certainly makes it appear probable that the reasoning on which the opinion is founded is

"correct, and that all cylinders would follow this law."

In the case of iron tubes, an experiment which any one can make is decisive as to the stretching. A leaden ring fitted on such a tube will stretch with it when strained, but will remain enlarged when the iron is permitted to regain its original size. Mr. Greener, of Birmingham, made a series of experiments with the barrel of a fowling-piece, having leaden rings at intervals on it, for the purpose of showing how much each part was enlarged during the discharge of the piece. Where he found this enlargement less than at other parts he concluded that the barrel was stronger than necessary, and modelled the next he made accordingly. The enlargement of tubes when pressed on from within, being thus proved beyond the possibility of doubt, the simultaneous diminution in the thickness of their sides will be readily admitted. "No person could expect a ring which fitted a little finger to be enlarged to fit a first finger without becoming thinner," as Capt. Blakely says; and as any thick cylinder or tube may be considered as composed of several concentric smaller ones, it is evident that each of these, by becoming thinner when stretched, loses some of its power of pressing the one above it. Here we have the whole of the very important theory of this able officer.

The method of constructing cannon which he advocates in accordance with it is, then, simply to form such parts of them as require great strength of concentric tubes, each slightly too small to go over the one below it without force; *the amount of this difference in size being so regulated that with a certain amount of pressure each tube shall be equally strained, or that the outside (which can be replaced if broken) shall be most strained.* One of these tubes should extend the entire length of the gun, the others may be formed of more convenient sizes. We really should like to see this system put into general practice. Its value can scarcely be over-estimated.

Captain Blakely honestly informs us that from the "Reports of Experiments on Metals for Cannon," he learns he is not the first person who proposed a remedy for the unequal straining of the parts of a gun. In 1851 Lieutenant Rodman of the United States Ordnance proposed, for that purpose, to cast guns hollow and cool them from within. On the 30th July of that year, at his suggestion an eight-inch gun was cast hollow by means of a core formed on a tube of cast-iron. Through this a stream of water was kept circulating until the gun was cool. By this means, Mr. Rodman made the inside solidify first. The next layer solidified, of course, at a greater temperature than that of the extreme inside at that moment, as this had already had a short time to cool and contract. Had the outside of the gun been kept liquid until all the rest had gradually become solid, giving out all heat through the core only, doubtless the gun would have been in a condition very nearly approaching that required by theory, so far as the initial tension on the external portions is concerned. As it was, the gun was much stronger than another cast solid at the same time, of the same size, and of the same metal. The latter burst after 73 rounds with 10 pounds of powder and one 64-pound shot; that cast hollow was fired 1,500 times with the same charge and is still sound. On the 21st August, 1851, two ten-inch guns were cast at New York from the same metal, one solid and one hollow. The latter was cooled from within like the eight-inch gun, but the outside was also allowed to cool, though more slowly. These guns were proved by repeated firing with 18 lbs. of gunpowder and one 124 lb. shot. The gun

cast solid burst at the twentieth round, the other stood 249 rounds. When examined afterwards, the gun cast hollow was found to be, in one part, fissured, the outside and inside having solidified before the middle. It is probable that even where no absolute fissure was found, the portion of metal intermediate between the two cooling surfaces was less dense than it should have been.

Captain Blakely does ample justice to Mr. Rodman's invention, but deems his own plan the better. "One advantage my plan certainly has," he says: "I can use, to obtain the greater part of the resistance required, a metal much stronger than cast iron, while retaining that metal for the interior of the tube, for which part it is so suited; thus securing the hardness and inflexibility of cast-iron, and the tensile force of the toughest steel. Wire even, the strongest form of iron or steel, can be used with great advantage in some cases. The saving in size of guns, therefore, in expense of transport would be enormous. This is, however, a very small matter, in my opinion, compared to the advantage of, by this means, being enabled to make cannon of a size and strength hitherto impossible, and still impossible by any means which do not ensure that each part shall do its work. Nothing would be so conducive to peace as arming the vulnerable parts of every coast with guns so powerful that one or two shells from them could destroy a ship. Few have any idea how inadequate to the end desired are the means often employed."

On another page we give a most interesting account of Captain Blakely's development of his invention, in his own language.

THE CASE OF HENRY CORT, AND HIS INVENTIONS IN THE MANUFACTURE OF BRITISH IRON.

BY
THOMAS WEBSTER, M.A., F.R.S., &c., Barrister-at-Law.
No. VI.

THE puddling process as described in the specification of Cort's second patent, with or without the working of the iron by the grooved rollers, was an improvement in the manufacture of bar from cast iron; the piling, faggoting, and heating of the iron in a hot-air furnace instead of a hollow fire under blast, and the working and welding of bar iron by the grooved rollers was an improvement in the application of bar iron, however made, to the purposes for which that material was required. The uses from iron made by the ordinary process, when piled, faggoted, and worked as described, were much better than had ever before been made of British iron; but such uses made of puddled iron, worked, piled, faggoted and rolled according to the complete invention, were equal to those theretofore made of foreign iron only; thus the home was placed upon an equality with the foreign manufacture.

Cort would appear to have freely invited the manufacturers of iron, of scientific persons, and of others interested in the subject at a very early stage of his discoveries. The following extract from a letter from the celebrated Watt to the equally celebrated Dr. Black, will be read with much interest. It bears date the 6th of June, 1784, that is, just after the specification of the first, and before the specification of the second patent:—

"Birmingham, June 6th, 1784.

"Previous to your letter I had heard much of Mr. Cort's process for making bars, and have seen a great deal of his iron; though I cannot perfectly agree with you as to its goodness, yet there is much ingenuity in the idea of forming

the bars in that manner, which is the only part of his process which has any pretensions to novelty. The kind of iron you describe is one of the modifications of cold short iron, and is known here by the emphatical name of *rotten-tough*. I have long known that almost any cold short iron may be brought to that state by rolling it very hot, or by drawing it across the anvil so as to spin the crystals into threads; and, by certain mechanical processes, good iron may be rendered cold short. Nevertheless in neither of these cases is the quality of the iron altered; the good iron continues strong, and the cold short is very weak. I look on Mr. Cort's iron as a cold short, whose crystals are spun out by the rolling, and which is mixed with a large quantity of half metallised earth. It is tender to the file, and soft to the hammer, rusts very readily, and ought never to be used where it is subjected to any strain, as it is very weak, therefore unfit for engine work, ship work, &c., but good for nails, because easily wrought; but then the nailors complain that it wastes more than the common cold short, I suppose because not so well freed from its cinder. I speak only of the iron made from cold short by this process. Good iron is hard under the hammer and stubborn to the chisel and file, breaks white, generally granulated, but the very best is fibrous, and white like silver. I find I am getting into a dissertation on iron which I must shorten. Mr. Cort has, as you observe, been most illiberally treated by the trade; they are ignorant brutes: but he exposed himself to it by exposing his process to them before it was perfect; and they saw his ignorance of the common operations of making iron, laughed at and despised him; yet they will contrive by some dirty evasion to use his process, or such parts as they like, without acknowledging him in it. I shall be glad to be able to be of any use to him."*

The iron referred to in this letter, both from the terms employed and from the period of the trials seen by Watt, must have been ordinary bar iron subjected to the treatment described in the specification of the first patent. The omission of all reference to the puddling process is conclusive on this point. The sympathy of Watt, then struggling with the opposition and difficulty of introducing the inventions the subject of his patent dated 5th January, 1769, and involved in litigation with those who sought to evade the moderate payment of a small portion of the saving which the immortal genius of the inventor had conferred upon them, must furnish an excuse for the severity of the language of a portion of that letter, and of the strictures upon persons who have shown no indisposition as a body to give due credit to Cort, though the sequel will show how much there is to justify the most severe censure on the indifference with which the nation has treated the family of one of its greatest benefactors. This letter is important as showing the attention which Cort's discoveries had then received from two of the most eminent men of the time.

The invention of Cort, as disclosed by the specifications of his two patents, taken out within thirteen months of each other, is puddling, piling, and faggoting, and heating in an air furnace, and working by grooved rollers; the air or reverberatory furnace was furnished with a hollow bottom, suitable for receiving the fluid mass and permitting it to be worked. This furnace was employed instead of the ordinary finery furnace theretofore used. Much has been said in the course of the controversy in this case respecting the construction of the furnace, the substitution of iron or cinder for sand

* See "Extracts from Mr. Watt's Correspondence," in the work entitled "Mechanical Inventions by James Watt, by Muirhead," Vol. II., p. 189.

bottoms in the puddling furnace, these and other subsequent improvements contributing to the certainty, perfection, and cheapness of the result are additions to, and in no respect deductions from the merit of Cort, who was the first to place the British in a position to compete with the foreign manufacturer.

The letter of Watt to Dr. Black is the earliest account that has been preserved of a cotemporary on the subject of Cort's inventions. The following letter from Alexander Raby, who had been in the iron trade between forty and fifty years, and well acquainted with its manufacture at least twenty years prior to Cort's inventions, will be read with interest; though not written for many years afterwards. It was addressed to Mr. Coningsby Cort on the occasion of the inquiry by the Parliamentary Committee, in 1812, into the merits of Cort's inventions:—

"Llanelly, June 20, 1812.

"DEAR SIR,—I have received your letter of the 15th inst. What I said to Mr. Giddy and Mr. Maddox upon your father's mode of making bar iron, I have not the least objection to state in writing.

"I was in the habit of intimacy with your father several years before he began his puddling system for making bar iron, and when he began it, and after he had used it some time, I was still of the unbelieving tribe, that thought it would never come to anything. I expressed myself so both publicly and privately at that time, and I may venture to say most other people in the iron trade thought of it as I did, and I am sure no man thought well enough of it for a long time after to claim the merit of the invention, nor was it thought of otherwise till your father, by his perseverance, had so far furthered the plan by producing most expeditiously large quantities of bar iron by working it in grooved rollers after being puddled, instead of under hammers, which invention of rolling bars was also entirely new and his own. Attempts had been made to roll round iron in hollows turned in rollers, but never to roll bar iron in grooved roll, which is very different, as round iron is not rolled in grooves, but in loose semicircles. No man, I think, will attempt to say he was the inventor of rolling bar iron in grooves, or to prove your father was not.

"Unbelieving as I was, I soon became a convert to his mode of puddling and rolling bar iron both as to quantity and quality. Some improvements soon also took place by first refining the pigs or cast iron before they puddled it, but it was obliged to be puddled before it was made into bars; nor could their refined metal be worked to profit or with expedition by any other mode than by puddling. I will venture to say that owing to that system and the use of grooved rolls, this kingdom is indebted for its present proud state of the iron trade, when instead of being obliged to bow down to the north of Europe for a scanty supply of that useful article at a very high price, we are enabled to supply all our own wants with an immense annual saving to the country. But was not only all Europe, but all the world to depend upon us for bar iron, Great Britain would be able to supply the whole, both good and cheap. And to whom is all this grand improvement and national benefit owing? and with whom did it originate but with your father? Envious persons may want to pervert the merit that is due to him, but when I recollect the trouble, pains, and expense he was at to make converts, so as to increase the quantity made by his mode when he was himself convinced of its utility, and the premium some great men then in the iron trade were in consequence thereof willing to pay for the use of his patent, surely that alone is sufficient to prove the inventions were

his own. I can only add, I am happy to be called upon to pay this small tribute to your father's memory, to whom I consider this kingdom, the world at large, and the iron trade in particular, greatly indebted.

"(Signed) ALEXANDER RABY."

The partner and associate with Cort in the business at Fontley, Adam Jellicoe, was, as appears by an agreement dated the 8th of Jan., 1781, entitled to one-half the premises, &c., on paying half the cost and one-half of all contracts and stock-in-trade, at a price to be settled by arbitration, and in consideration of finding the necessary capital was to participate equally in the profits of the trade. It appears that Cort advanced £20,000, and Jellicoe £27,500 on the Fontley business. In one respect Cort was more fortunate than many of his class; the practical instinct and indomitable perseverance, the characteristics of his inventive genius, were not smothered by the want of pecuniary means to demonstrate the truth of his speculations. The manufacture by his process from the commonest description of cast iron of iron equal and superior to the best qualities of foreign iron became an established and admitted fact. Immediately after the date of his second patent, Cort was able to obtain the ear and command the attention of the public departments to his invention, which in 1785 and 1786 was made the subject of trials in the dockyards of Portsmouth, Deptford, Woolwich, Sheerness, Chatham, and Plymouth. The result of these trials was published in 1787, accompanied by a statement of facts authenticated by the authority of Lord Sheffield, Dr. Joseph Black, and David Hartley.

The following extracts from original documents which have been preserved, and from the printed statement so authenticated, will be read with interest:—

"Navy Office, 13th June, 1783.

"Messrs. CORT AND JELlicoe.—In return to your letter of yesterday requesting that directions may be given to inspect the nature of your new-invented method of working iron, acquaint you that we have directed some of Portsmouth officers with the master-smith to proceed to the works and report fully their opinion.

(Signed) "CHAS. MIDDLETON,
"J. WILLIAMS,
"GEO. ROGERS."

"Portsmouth Dock, 7th July, 1783.

"HONOURABLE SIRs.—In obedience to your directions of the 13th inst, in consequence of a letter from Messrs. Cort and Jellicoe, requesting directions may be given to inspect the nature of their new-invented method of preparing, welding, and working various sorts of iron, that the master-shipwright and his first assistant, with the storekeeper and master-smith, should proceed to the works and thoroughly examine the process they make use of, and report fully their opinion thereon, returning the enclosed with their answer.

"In answer, pray leave to acquaint you that we have been to Messrs. Cort and Jellicoe's mills at Fontley, and thoroughly examined the process they make use of in preparing, welding, and working various sorts of iron, which they do by putting the iron designed to be worked into an air furnace, where it remains until it is so hot as to be between a welding and a fluid state, when it is either worked under a forge-hammer of 7 or 8 cwt. or passed between two rollers of about 9 cwt. each, which immediately and very visibly destroys the greatest part of the dross and impurities from the said iron, and if required will also weld two bars together at the same time, as well as bring the most brittle

iron into a malleable and tough state by the above process, equal to the best Orground iron, which we flatter ourselves will be clearly investigated by the following experiments:—

"By putting a piece of the best Orground iron, marked (L); of nine pounds weight into the air furnace, and when so hot as above described took out and passed between the rollers, whose pressure is such as to discharge the greatest part of the dross and impurities from the said iron; for on weighing it after it had passed through the above process we found it weighed only 8½ lbs., so that it discharged ¼ of a pound in nine.

"We also tried three other pieces of iron of the different weights and qualities by the above process, which are as follows, viz., a piece of the 2nd sort of iron of 9 lbs., which on weighing after it had passed the above process weighed only 6½ lbs., so that it discharged 2½ lbs.; a piece of the 3rd sort of 5½ lbs. weighed after passing the above process, only 3½ lbs.; a piece of very bad iron of 4½ lbs. weighed after passing the above process only 2½ lbs.; by which it appears that the dross discharged by this process is in proportion to the goodness of the several sorts of iron; and by every trial we made, as far as we could discover by the different discharges of the dross and impurities from the different sorts of iron, it all became equally pure to any iron that can be manufactured. We also had some faggots of old iron hoops, and of the smallest sort of Birstrel iron put into the air-furnace and worked under a forge-hammer of 7 or 8 cwt., which welded it so entirely as to make it perfectly one solid body, and at the same time also discharged the greatest part of the dross, which we proved by passing it afterwards between the rollers and slitting into hoops, and another piece into bars of a half-inch square, and then drawing into bolt staves, which was very good. We also made a tackle-hook from some of the same iron, and put it cold under the forge-hammer, which did not break it. We are therefore humbly of opinion, from the many experiments we have made both from old and Birstrel iron, &c., when properly manufactured, as set forth on the other side, by being heated to a proper heat in the air-furnace and worked under the rollers or forge-hammers as therein described, is very proper iron for making mooring-chains, bolt-staves, tackle-hooks, &c., &c., &c., or any other uses it may be wanted, for this or any of His Majesty's yards.

"We had also two links of large mooring-chains drawn from the air furnace, under the forge-hammer, which we found to be quite solid and much tougher than those made from the common forge; and herewith we return Messrs. Cort and Jellicoe's letter, which being submitted,

"We remain, Honourable Sirs,

"Your most obedient Servants,

"(Signed) GEO. WHITE, WM. RULE,
"J. BADCOCK, J. GREENWAY."

Other letters and communications passed about the same time in reference to the trials, which established conclusively to the satisfaction of the authorities the superiority of the iron made according to Cort's processes of manufacture.

THE GLOBE TELEGRAPH.

In a late number a review was given of Mr. Beardmore's pamphlet upon "The Globe Telegraph," under which title was proposed a system of electro-telegraphic communication, which bids fair to solve the difficulties which attend the transmission of signals in long submarine wires. To most of our professional readers these difficulties, and the method by which it is now shown they may, in all probability, be overcome, are already familiar; but we think it necessary, in order that the general reader may be *au courant* with a subject involving, perhaps, the very possibility of successfully establishing a telegraphic link between the Old World and the New, to give a brief *aperçu* of this plan, and of the advantages said to be derived from it.

The galvanic arrangement employed by the patentees of the "Globe Telegraph" consists simply of the "two dissimilar metals" with which Subzar experimented, and the effect of which in contact was (some fifty years afterwards), investigated by Galvani, and made the subject of a science by Volta. The battery arrangement discovered by the latter philosopher in his *Coursane de Tusces*, consisting of a series of alternations of dissimilar metals contained in separate vessels, and connected one with the other by a metallic wire, is relinquished for a single couple, the amount of surface of which is regulated according to the distance between the metals; and the wire, by means of which a metallic connection is established between, then becomes the medium through which the current is rendered available.

By increasing the number of the galvanic couples, and by immersing them in an active chemical agent, Volta was enabled to obtain the energetic action due to what is termed "tension" electricity. By "tension," in opposition to "quantity," is understood that property by which an electric current produces in a higher degree the effects of muscular disturbance in animal bodies, and of electro-chemical decomposition in inorganic compounds. But it is by no means necessary that this property should exist in any high degree for the production of those phenomena on which depends the transmission of electric signals, and, on the other hand, it is now evident that the employment of high tension electricity is productive of serious disadvantages as regards "induced currents" and the loss of electricity. The usual electric signal consists in the deflection of a magnetic needle; and this deflection may be produced with a current of very low tension by means of a *short* coil of a *thick* wire, upon which the ordinary telegraphic current would produce a scarcely perceptible effect. This being the case, the employment of tension electricity, with *long* coils of *fine* wire, offering a considerable resistance to the circuit, certainly appears anomalous; and the substitution of the contrary conditions would be a step in advance in the art of electro-telegraphy.

But the current produced by the simple galvanic couple possesses an important advantage over any other "quantity" arrangement, inasmuch as the electricity has no tendency to escape through the earth from an imperfectly insulated wire. In the proposed arrangement any deficiency of insulation can only interfere with the transmission of the current by causing the wire to act as a voltaic element, neutralising to a greater or

less extent the available electricity of the plates. The importance of this consideration becomes obvious when we take into account the enormous loss of power which must occur in submarine circuits, where the imperfectly insulating covering of the wire is exposed to the constant action of high-tension electricity.

In April of the present year a trial of the new system was made between Guernsey and Southampton, in which, with single plates of zinc and copper, 110 miles apart, and less than three square feet in size, sufficient electro-motive force was obtained to work a Siemens instrument. Little attention appears to have been directed to this experiment, which we would now offer for the consideration of those who were present at the reading of Mr. Varley's paper at the Society of Arts in March last, under the impression that it might throw some new light upon the difficulties of submarine telegraphy.

MONEY-MAKING AT THE ROYAL MINT.

No. VII.

In order to make our explanation of the mode of getting up medals yet more clear and explicit it must be stated that there are two machines employed at the Mint for lettering, after they are struck, the edges of those badges of honourable distinction. These machines are so constructed as to indent, by the aid of small steel type, the rank, name, and ship, or regiment of each person destined to receive a medal, upon its edge. As may be imagined, this operation is a tedious one, and when many have to be lettered in a comparatively short space of time, a compositor from an ordinary printing office is engaged on the duty. In the case of the Crimean medals—of which we believe, so indiscriminately were they bestowed upon English, French, Sardinian, and Turkish soldiers and others, 400,000 were distributed—it was found impossible to letter more than a select few. It would have been exceedingly difficult to collect the names of the motley host which comprised the allied forces, and more difficult, perhaps, to decipher those names, or find space for them with the other particulars, and the clips, upon the limited circumference of the medal. Officers and men, however, of the British Naval and Military Services had the privilege allowed them of returning, through the Admiralty or the War Office, their medals to the Mint for the purpose of having their names, &c., impressed upon them, and many, we believe, availed themselves of the opportunity.

The machines for effecting the object are small, and worked by hand. In one the medals may be lettered *after* the clips have been attached, and in the other *before*. In the first the medal is put into the machine vertically, and the type is made to travel underneath it; in the second, which is that usually employed, and which we shall therefore more fully describe, the medal is placed horizontally in the machine, and made to revolve against the type. This machine consists of a firm oaken bed, supported on four legs, and fitted with a hand-wheel and crank, calculated to give to a square horizontal bar of iron working in a planed groove a travel of some six inches. Parallel with this iron bar, which rises to perhaps $\frac{3}{4}$ of an inch above the groove, and to one side of which is attached a boxwood cheek—parallel with this is a stationary recess for holding the type case. Between the cheek and the type case there is a space slightly less than the diameter of the medal. Within this space the medals, flatly laid, receive their indentations. The compositor, sitting at a table beside the machine, with his war office or Admiralty "copy" before him, and his alphabetically-arranged type near at hand, has set up in the little case, about 4 inches in length, say the name of "Serjeant Major John Jackson, 60th Rifles," or of "Admiral Sir Charles Napier, H.M.S. Undaunted." Well, he next carefully places the

case, which is quite straight, and allows the letters to project equally throughout, in the machine, and lays the medal in the space alluded to. He now puts his hand to the wheel, and turns it until the sliding bar advances with its wooden cheek, and the latter catches the edge of the medal. Continuing now, per wheel, the forward pressure, the medal is made to revolve in front of the steel letters, and to take from them the requisite inscription. After passing beyond the case of the type the medal is necessarily released, and if on examination found free from error or imperfection, is placed in a numbered envelope, and for the present set aside. Mr. Compositor now looks to the next name on his list, re-sets the type in accordance therewith, and repeats the operation as described, and to be continued until the list is completed; but it is unavoidably a slow process.

The Mint may at this stage be said to wash its hands of medals, for they are despatched after lettering to the Horse Guards or the Admiralty, and thence to the court jewellers, Messrs. Hunt and Roskell, to be further fitted with clips, ribands, and clasps, one of the latter, indeed, being given for each important action in which its recipient may have been engaged. The jewellers return them to the Government office, to which they pertain, and soon they are seen decorating the breasts of those who have nobly earned them. Besides the general medals given for the Kaffir, the Russian, the Persian, and the Indian wars, there are occasionally struck and distributed particular decorations for "meritorious service," "distinguished conduct in the field," and for "long service and good conduct." The medals in all cases are of the same intrinsic value, weight, and material, namely, 6s. 6d., one ounce, and of fine silver. The mountings, labour, &c., make them cost the State, however, about eight shillings each.

Thus much on medals; now let us revert to a process intimately connected with money and medal making—that of the conversion of square bars of cast steel into dies. Without these no legitimate coining can go on, whatever the ladle and mould, in an illegitimate sense, may accomplish "down Whitechapel way." All the dies used in the Royal Mint are made in that establishment, and it would be improper to conclude our series of papers on money-making without allusion to the manner in which they are manufactured. The bars of steel intended for conversion into coining dies, are selected from the very finest that can be produced. The Messrs. Turton, of Sheffield, have obtained honourable mention for the rare quality of the article for the especial purpose which they have supplied. A much larger percentage of coins are obtained, we are credibly informed, from dies made of their steel, than from those got up from any other. Supposing that we were about to carry out the decimal system of coinage as shadowed forth lately in our own columns, and that the engraver of the Royal Mint had received instructions to prepare designs and get up dies for the one or two new coins which would thus become necessary, he would commence his important duty much after the following fashion:—

With pencil, paper, and compasses, he would take the initiatory step, that of sketching the obverse and reverse of the coin—say the cent, for example. Having satisfied himself upon the proportions, devices, and inscription of the embryo pieces, the engraver would next obtain a piece of steel cut from a square bar, of the best quality, forged into the cylindrical forms of the proper dimensions, faced in the lathe, and in a soft state. To the faced ends of this he would transfer with pointed gravers the design determined on. The next operation would be to commence engraving that design on the surface of the steel with small tools prepared for the purpose. After, as may be supposed, a very considerable amount of sedentary and tedious labour, and no ordinary exertion of patience, there appears upon the surface of the steel a very perfect copy in *intaglio* of the original design. Repeated impressions taken from this in clay of a peculiar nature and colour—hard and

grayish white—enable the worker to test the finish of his work and to examine the fineness of his lines and the general effect they are likely to produce as a coin. Satisfied at length that all is well, and that retouchings would be but to “paint the lily,” the engraver gets all superfluous steel turned off in the lathe, and the diameter and height of this *matrix*, as it is now called, made precisely what he wishes them to be. Then comes a delicate and exceedingly important task—that of hardening—and here practical difficulties arise which, if not successfully overcome, may mar all his previous labours.

Above all things, the engraved face of the *matrix* must be protected from the action of fire or water. In order to accomplish this protection various substances have been employed; but mixed oil and lamp black answers pretty well. This composition, in proper proportions to form a paste, is spread thinly over the engraved work of the *matrix*, which is next placed face downwards, and surrounded by powdered animal charcoal. It is heated to a particular temperature, and then plunged into cold water. In this it is kept, held by a pair of tongs, in a state of agitation until all ebullition ceases. Much of the art of die-hardening depends on practice, and nothing short of extensive practice and a perfect knowledge of the chemical and mechanical properties of the steel to be dealt with can qualify workmen for the duty. Constant practice in the same round of operations at the Mint no doubt ensures success in almost all cases of hardening. We will suppose that it has so resulted in the case of our imaginary cent *matrix*, which the engraver, after tempering, pronounces to be good and serviceable. His next want is that of a “*punch*”—not a copy of our facetious friend over the way—but a steel punch. In order to obtain this, another piece of the same steel bar which has so far “worked” well is cut off, forged, turned, and prepared. Instead of having this will-be *punch* turned flatly on the end, it is made flatly conical, the apex being a point. With this point uppermost the piece of softened steel is now placed on the solid bed of a heavy press, to be worked by hand, though having its screw and fly-arms so arranged as that they be made to take three or four complete revolutions upwards, and then be thrown down with great momentum. The *matrix*, like the upper die in the coining press, is fastened to the screw of the press, and as all is ready for the next stage of die-making, we may suppose that the workmen have raised the screw and *matrix* to the required height. All is adjusted below, and the fly-arms released spin round with great and increasing velocity until the engraved face of the *matrix* meets in violent contact the apex or point of the *punch*, and you might suppose that the engraver’s work was marred by the blow. Now the press rebounds, the workmen catch the fly-arms, and on examining the *matrix* you find it none the worse. The punch shows the valuable effect of the concussion, however, in having obtained to some extent, if not completely, a faithful copy in relief of the engraved *matrix*. This latter may now indeed be laid aside, its mission for the present being ended. The *punch* has, however, to be passed through the ordeal of hardening before becoming ready for its arduous task of giving impression to thousands, and it may be tens of thousands of money-making dies. The hardening and tempering in this instance are performed in a manner precisely similar to that described above, and at the Mint failures are extremely rare. The punches for both obverse and reverse sides of a coin are prepared in the same way, and once these are perfectly struck, hardened, tempered, and, perhaps, retouched by the engraver, they are in a condition to allow dies to be multiplied from them almost *ad infinitum*. Pieces of steel are now cut from the bar and forged to the circular form, then turned flatly conical on one end, softened to the lowest point, and sent forward to the *die multiplying press*. Here they are placed one by one on the bed of the press and underneath the *punch*, which is made to strike them with all the accumulated force of sundry revolutions of the weighted

screw, if the dies are of large size, and with modified intensity if the dies are small. Repeated thumpings transfer the relief engraving of the punch to the turned end of the die, which perhaps, too, will require one or two annealings before getting an *intaglio* impression perfectly representing the device of the punch. This, however, being accomplished satisfactorily in a number of cases, a batch is sent off to the die-turning shop. This is fitted with several lathes—it must be admitted rather antiquated—in which the superfluous steel is turned off and the dies made of the proper diameter, height, and shape for fitting the die holders of the coining presses. Next they are hardened, then their faces are polished by being held against a rapidly-running disc of iron, and lastly, they are brought by tempering to a colour very much resembling the hue of our southern corn-fields at this hour—a “*dark straw*.” The average number of coins which a pair of dies should produce is 30,000, and more ought not to be struck from them. The dies for medals are got up in a manner closely resembling that in which coining dies are prepared, but of course from their larger size and bolder engraving, they give in every stage of manufacture more trouble.

It may be said, too, that in the engraver’s department at the Royal Mint there is a machine, which we have seen, for copying, on a larger or smaller scale, an engraved device of any sort; for instance, supposing that, by some unhappy dispensation of Providence, a new monarch had succeeded to the throne of these realms, it would become necessary to issue a new set of coins, from the sovereign downwards. Well, then, by aid of the copying machine in question, which is of delicate construction and very perfect in its details, the engraver, after designing and engraving one obverse of large size, would be enabled to produce a series of small copies in steel down to the threepenny-piece size. At one end of the machine he would fix his engraved die, and at the other a plain piece of steel. By means of a treadle he would put both these in motion. He would next cause a steel pin fastened at right angles to a square bar of iron, having a moveable fulcrum, to be brought forward to the engraved surface he wishes to copy. This pin is kept up to its work by means of a weight and lever. At the other end of the iron bar, which is placed parallel with the front of the machine, would be fixed a small cutting tool. This would, therefore, when the machine was kept in motion, cut from the surface of the softened piece of steel just as much metal as the pin traversing over the whole engraved face of the die at the other end would allow; and, in fact, would copy it, on either a larger or smaller scale, in proportion to the distances of the fulcrum from the cutting-tool and the guide-pin. The coinage of King William IV. is remarkable for the accurate profile of His Majesty upon all the pieces of money comprising it. The copying machine here referred to may be thanked for preserving so closely the lineaments of the monarch. Mr. W. Wyon copied and engraved from a life-like bust by Chantry the head for the William IV. half-crown, and all the other dies for the coinage were the work of the copying machine. Those who have not compared the coins of the various denominations of this reign with each other may well do so—microscopically, or otherwise—and they cannot fail to observe their *vraisemblance*. Attached to the die department of the Royal Mint there is a die museum, of the contents of which a carefully-arranged chronological catalogue in MSS. exists. Visitors, on application, are allowed to inspect the contents of this numismatically interesting apartment. The oldest die in the place is of the date 1272, and it is a rare specimen of the art of engraving at that remote era. The *Simon* petition crown die is among the curiosities of the die museum of the Mint; but to catalogue all the specimens of this species of manufacture on its shelves would be to absorb an amount of space which cannot be spared.

It is hoped that the main points in the art of Money-making, Medal-striking, and Die-manufacturing have been revealed to the public through

our pages with sufficient clearness, and that our labour in the preparation of the series of papers on these subjects—of which this is the last—has not been labour lost.

As it is possible that some of our readers may require to put the machinery of the Mint in motion on their own accounts some day, we may tell them that in order to do so they are only required to be possessed of £10,000 worth of gold, and to observe the following (abstract of) regulations:—

1st. The Mint receives gold bullion for coinage on Tuesdays, Thursdays, and Saturdays, from 12 to 2.

2nd. Any persons intending to deliver gold into the Mint for coinage must give a week’s notice of their intention by letter addressed to the Master of the Mint.

3rd. Before delivery, the person delivering the bullion must make a written statement in duplicate on forms supplied to him at the Mint, of the marks of each ingot, the “report” thereon of the assayer, upon whose assay he purchased it, and the name of that assayer.

4th. All the regulations with regard to weighing through Mint office scales, entries of weights, &c., as described in our account previously published of receipt of bullion from the Bank, must be attended to.

5th. A new assay by Mint assayer, and comparisons, with report of private assayer, necessary.

6th. The bullion must not be brittle.

7th. Arbitration, if the assayers differ as to the “betterness” or “worseness” of the bullion.

8th. On the completion of the coin notice shall be sent to the importer, and a time fixed for its delivery to him, when the same weight in gold coins at the standard weight at which the ingots were received will be delivered to him *without any charge whatever*!

The ninth and last clause of these regulations—which are not, for obvious reasons, given *in extenso*, but which we shall be happy to supply to any would-be coiner—the ninth clause is the most important, because it demonstrates that gold coinages are executed at the public expense. Some member of the Rothschild family was, we believe, the only private individual who has had the honour and profit of working the Mint machinery as yet.

Now, as regards the means of gaining admission to the Royal Mint for the purpose of viewing the operations going on there, and of which it is to be feared our pen may not have conveyed so complete a literary daugerröotype as might fain be wished—as regards means of gaining admission, we may furnish the principal regulations bearing thereon:—

“Tickets of admission to view the Mint will only be given to persons known to the Master, or to one of the principal officers of the Mint.”

This regulation, it may be observed, receives a very liberal interpretation at the hands of the present Master of the Mint. “Persons coming with a ticket to view the Mint are to be received at the principal entrance by the visitor’s messenger, who is to require the names of each party—which must not exceed six persons—to be written on the back of the ticket, and then to conduct them in succession round the following places, taking care that the whole time devoted to one party does not exceed 45 minutes:—The silver melting-house, the gold melting-house, the rolling-room, the adjusting-room, the cutting press-room, the marking-room, the annealing-room, the weighing-machine-room, the coining press-room, the die-multiplying press-room, and the die-turning shop.” A pretty considerable “round” for three-quarters of an hour with “running” explanations by the messenger. The visitor’s messenger enjoins those under his care “not to touch anything” in the rooms, and he in his turn is cautioned by regulation not to touch any gratuity from any visitor, nor allow any other person to do so.

Such are the main features of the regulations made for the admission of strangers to the Mint, and with them we say to those who have kindly followed us to the end—farewell!

THE AMERICAN SUBMARINE WAR VESSEL.

SOME months since, the *Times* startled many persons by an exciting account of a submarine war-vessel. Mr. W. Delaney, of Chicago, the gentleman who came here to work the plan, has obtained a patent for the vessel, which he describes in his specification in the following terms:—

"This invention has for its object improvements in submarine boats or vessels, and in apparatus for working under water. A boat or vessel is constructed of plate iron, or it may be of wood or other material, supported by a frame of sufficient strength. This boat or vessel is closed on all sides; it is elliptical, or rather egg-shaped in transverse section, and runs off to a point at both ends; one end being, however, more rounded than the other, and its length is several times its greatest diameter; and at the top, bottom, and sides four or other number of keels are fixed to keep the vessel steady in the water. Within the boat or vessel are two strong metal tanks, into one of which air can be forced by an air-pump. This tank is connected with the second tank by a pipe furnished with a cock, and the second tank also communicates by a pipe with the water exterior of the boat or vessel; so that a person within the boat or vessel can fill this tank with water, and thus increase the weight of the boat or vessel so as to cause it to sink, or by allowing the air to pass from the air-tank to the water-tank, the water may be again ejected, so as to lighten the vessel sufficiently to cause it to rise to the surface. Through one end of the vessel a hollow shaft passes by a ball and socket-joint, and on this shaft a rudder is mounted. Beyond the rudder there is a screw propeller, which is driven from the interior by an axis passing through the hollow shaft of the rudder. By this propeller the vessel may be propelled in any desired direction. A similar screw may be placed at the other end of the vessel if thought desirable. The persons within the boat or vessel are supplied with air from time to time from the air-tank, and the vitiated air is allowed to escape from a cock into the exterior water. Double doors are formed in the top, bottom, and sides of the vessel, and these may be opened beneath the water to allow of ballast being passed out when necessary, and for other purposes. In conjunction with this boat or vessel a diving armour is employed, so that when the boat or vessel arrives at a point where work is to be done a diver may leave the same to do whatever may be required. This armour is formed of metal, the moving parts being so fitted and jointed together that the pressure of the water may be sustained by the armour and not communicated to the body of the diver. Through the sides of the armour a number of tongs pass, with which the diver can hold any tool with which he has to work, or any other article. These tongs pass through ball and socket joints, and are arranged to be readily acted on from the interior of the armour, so as to cause them to open and close. Into the ball and socket joints any tools may be fitted, and these also serve to pass short tools from the exterior to the interior of the armour as may be required. In order to facilitate the movement of the diver a screw propeller is attached to the front of the armour. The diver is supplied with air from the air-tank within the boat or vessel, or otherwise, and he also carries on his back a reservoir of compressed air, which enables him temporarily to disconnect the hose if required. The rope by which the diver is lowered is also so arranged that the diver can disconnect it if he desires. Exterior of the armour is an elastic bag, into which the diver admits air, so as to inflate it when he wishes to use the surface. A lamp is mounted within the armour, and in front of the same is a bull's eye, which concentrates the light on objects in front of the diver. The submarine boat or vessel is in some cases fitted with steam-engines, to propel it more rapidly when the boat or vessel is at the surface of the water. The same power also serves to pump air into the tank."

THE PATENT TRAVERSING DRILLING MACHINERY OF MESSRS. SHARP, STEWART, AND CO.

Those who are acquainted with the process of slotting holes through a considerable thickness of wrought-iron are well aware of the amount of trouble and time which is expended upon it under the old system of operation. There is, perhaps, no work so expensive to the mechanical engineer as this, and when complete it is but rarely satisfactory. We have now the pleasure of laying before our readers a description, with engravings, of a machine invented and manufactured by Messrs. Sharp, Stewart, and Co., of Manchester, adapted to the performance of the work in question. It does its work with such success that the cost of labour has been reduced some 90 per cent., and at the same time almost mathematical certainty has been secured. As an instance: a slot-hole 6 inches long, $\frac{1}{2}$ wide, and $5\frac{1}{2}$ inches deep, formed in the ordinary manner, would be produced in 32 hours at a cost of £1 2s. 2d., three files being expended upon the work. This can now be effected by means of the traversing drilling machine in less than 14 hours, at a cost of only 2 shillings, in the case of one workman having three such drills to attend to. With this fact before us it will be needless for us to expatiate further upon the advantages of such a system. We proceed therefore, to describe and illustrate the machine itself, and shall then enumerate the various purposes to which, up to the present time, it has been applied.

The general action of the ordinary drilling machine is well understood. The constant revolution of two paring edges round a common centre is employed in such machines to produce a vertical hole. If, then, instead of giving the tool a simple vertical feed, we endue it with a reciprocating motion, altering the form of its end so as to produce a double rounded nose with cutting edges, and taking away the centre clearing point, which is not now required, we are enabled to form a long slotted hole instead of a circular one. The vertical feed in this case must of course be given at each end of the traverse, so as to insure the plane of the cut being horizontal from end to end. Fig. 1 shows the various forms of the tools made for use in this machine. The first two are roughing tools, for small or large diameters. It will be noticed that in the large size the tools are adjustable and secured by means of set screws at their lower ends. The third and fourth tools shown are rose bits whose serrated edges are curved; these are used for finishing the work. Plans also of all the tools are shown below the elevations. The roughing-out tools on the average require sharpening but once in the week, and the rose bits but once in six weeks. Having investigated the form of the tools in use, we pass on to the consideration of the machine itself, and its mode of action.

In fig. 2 we have given a perspective view of one of the single traversing drilling machines; it consists of a strong frame of cast-iron after the fashion of a lathe bed supported upon a standard at each end. The top surface of this bed is planed true, and fitted with a hollow or box standard carrying the drilling spindle, which is worked in the ordinary manner by bevel wheels; this standard is caused to travel backwards and forwards upon the bed by the circular motion of a horizontal plate, which is slotted and graduated

so that its projecting bearing can be shifted, and the reciprocation varied at pleasure. The spindle of the horizontal plate is driven by the lower shaft, which is figured 4, by means of speed pulleys from the upper or first driving shaft B. Of course a regular velocity in the traverse cannot be attained by a simple crank motion, as the speed will gradually diminish to nothing at the extremities of the traverse; but this is obviated in a very ingenious manner by the introduction of a pair of eccentric-toothed wheels such as are shown in fig. 3. These are so arranged that the proportion of their working diameters varies so as to overcome the difficulty which would otherwise arise. The position of the connecting rod is shown by the letters A, B, in Fig. 3. Underneath the horizontal plate, which is

lettered *C*, Fig. 2, is a roller-path, with a cam rising in two places. Rolling upon this is a wheel at the end of the crank lever *D*, which, by means of a short connecting rod, imparts motion to the lever *E*, which is fitted with a pawl playing upon a small ratchet, which is fixed upon a shaft, and thence by the inclined spindle *F* to the upper wheel, which, working in a rack, feeds down the drill; by this means the cut is given at both ends of the traverse. The handle *G* is used for working the inclined spindle, when required, by hand. In front of the bed or frame is fixed an adjustable table, similar to those used in the ordinary shaping machines, with adjusting screws for elevating or moving it horizontally so as to bring the work into its proper position. The spindles for this purpose are shown by the letters *H* and *I*. The upper chamber of the standard supporting the drill spindle is used as a receptacle for oil to be fed down to the cutting edge as required. These machines are often made longer in the bed and fitted with double standards, so that the operation can be carried on at both ends of a piece of work at one time.

Fig. 4 shows examples of two applications of this new system of work. The first is the stump end of a connecting rod and the strap showing the slot holes as also the transverse opening, all of which can be formed in this manner. Next to this is shown a pair of forked ends forged together in the solid, and these, when slotted out by the traverse motion, present the appearance which is shown by the letter *A*; they have after this to be merely divided, and the holes being drilled through, to be rounded in the

shaping machine. The formation of keyways in crank and other shafts, and oil channels in brasses, &c., are amongst the many applications of the traverse drill. When the traverse is not needed the machine can be used as an ordinary vertical drill, so that it is an exceedingly useful tool in the engine and machine shop, and will, we doubt not, ere long entirely do away with hand labour for the purposes for which it is adapted.

THE MANUFACTURE OF CANNON.

By Captain BLAKELY, R.A., M.R.I.A., F.R.G.S., &c.*

My first experiment was to shrink a heated wrought-iron ring over one of cast iron. The result was the compression of the latter to an extent I by no means expected, the wrought iron being only slightly expanded. When separated, both tubes regained their original size.

I next made an 18-pounder gun, formed of a tube of cast iron, 5½ inches in diameter, and 1½ inch thick, over which were shrunk, side by side, short cylinders of wrought iron, the thickest of which was 2 inches. To resist the force of the gunpowder, therefore, this gun had a total thickness where strongest of only 3½ inches; that of a service cast-iron 18-pounder being upwards of 5½ inches. Yet the lesser thickness was quite sufficient, even though the initial strain, calculated as necessary on the outer tubes, had been but very roughly approximated. As a cast-iron tube, 1½ inch thick, was insufficient to resist the longitudinal strain, and as the wrought-iron cylinders were not joined, but merely placed side by side,

* From a paper read at the United Service Institution.

four rods were used to give additional strength lengthways. These were fastened at one end to a ring carrying the trunnions, and at the other to an iron plate, which they pressed against the breech end of the gun. Two of these rods and the trunnions are not shown in the longitudinal sections, but are seen in the cross-sections. This gun was much stronger than necessary at the front part; indeed everywhere, except just round the seat of the charge. I regret, now, that I only fired it enough to prove that it was an efficient 18-pounder gun; had I continued till it burst, its strength relatively to service-guns would have been more definitely known. Being desirous, however, before injuring it to find out if a still thinner cast-iron core would suffice, I had this 18-pounder bored out to the size of a 24-pounder. Unluckily, in so doing the bore was not made in the centre, only half-an-inch of cast iron being left at one side of it. Even in this state, however, it bore, without injury, several hours' firing with charges varying from one shot and four pounds of powder, to one shot, two wads, and eight pounds of powder. It burst at the third round with the latter charge. This great strength was unexpected, the thickness of metal round the charge being only 2½ inches; whereas, in a service 24-pounder it is upwards of 6 inches. My gun, too, had much less windage. It weighed 15 cwt., less by 5 cwt. than the reamed-out 24-pounders which are used with a service-charge of 2 lbs. 8 ozs. of powder. The iron service 24-pounder for an eight-pound charge weighs 48 cwt.

The next experiment I made was to get a 9-pounder service-gun turned down cylindrical from the trunnions to the breech, and on this part to place wrought-iron tubes nearly the exact size and weight of the portion of metal removed, but just the necessary fraction of an inch smaller. The wrought-iron tubes had dove-tailed flanges, so that the one clamping the other gave some longitudinal strength; not that I think this was necessary. Indeed, if outer tubes had been placed merely half-way to the trunnions, strength enough would have been attained. This gun was fired as follows:—

2 rounds with 8 lbs. of powder and 2 shot.			
86	"	3	"
26	"	4	"
5	"	5	"

1	"	6	"
1	"	6	"
1	"	6	"
1	"	6	"
1	"	6	"
158	"	6	"

A cast-iron service-gun, of about the same size and weight, was fired, round for round, with this gun until the 110th round, with six pounds of powder and two shot, when the cast-iron gun burst. The superiority of mine was so evident, that Her Majesty's Government had a 68-pounder and a 10-inch gun made almost on the model of it. The 68-pounder made in 1857 will, I hope, be tested this year or next.

My fourth gun was an 18-pounder. The inner cast-iron tube was only 1 inch thick, and open at both ends, the breech being closed by a plug. This was decidedly a mistake, throwing too great a strain on the four longitudinal bolts with which this gun, like my first, was provided, though these are not shown in the figure. Over the cast-iron tube I put two layers of wrought-iron tubes; the first broad, thin tubes (five-eighths of an inch thick), the outer ones thicker and shorter. By making the two layers break joint, additional stiffness was obtained. This gun was fired—

1 round with 6 lbs. of powder, 1 wad and 1 shot			
1	"	9	"
1	"	10½	"
1	"	12	"

At this round the four bolts gave way, although each was two five-eighths inches thick—the four united being equal to a solid bar the size of the

bore of the gun. The rest of the gun was uninjured, so that this trial was a great success so far as the method of obtaining lateral strength was concerned, the sides being at the thickest part only three five-eighths inches thick. The charge which broke this gun was twelve pounds of powder—double the service-charge for guns more than double the weight, and four times the service charge of the 21-cwt. service gun. I had this gun remade with four bolts of the best charcoal iron; but they, too, broke, without injury to the tubular part. Though so far most satisfactory, this result made me decide not again to leave the entire longitudinal strain to be borne by outer bars.

My fifth gun, which I made in 1856—those I have mentioned having been made in 1855—was a 12-pounder. The longitudinal strain I divided between four bars, attached as in former guns, and the cast-iron central tube which took half this strain, its breech-end, to insure this, having an aperture only half the size of the bore. This gun had two layers of wrought iron cylinders. The manufacture of this gun showed me the great uncertainty of the result of shrinking heated iron tubes. Those for this gun had been made of the same iron, carefully bored to the same diameter, and heated equally; yet about two feet in front of the breech they had compressed the cast-iron core so much more than in other parts, that the bore was there $\frac{1}{4}$ th of an inch less. This determined me in future always to force the outer tubes on cold, making the outside of the inner tube a little conical tapering towards the breech-end. Great accuracy can thus be obtained. Indeed, the method of heating and shrinking on the tubes I had only adopted as a cheaper makeshift for the first few experimental guns. Knowing from former experiments that it would be useless to attempt to burst this gun with ordinary charges, it being much stronger than any former ones, I had long iron cylinders cast and turned accurately to fit the bore. Unfortunately, I had too great confidence in it; and, instead of waiting a day or two and having the compressed part again bored out cylindrical, I fired these closely-fitting cylinders from it. Having put in the powder for the fourth or fifth round, the cylinder was introduced, but stuck in the narrow part, and we could not get it out again. Thinking that the gun was too strong to be burst by gunpowder in any way, I fired it. It burst. Nothing could have been more injudicious than firing the gun so loaded. Not having any means of calculating the strain on it, nothing would have been proved had it remained sound. I should have been particularly careful, too, of this fifth gun, because I could not afford to make a sixth. This fifth gun proved nothing; but in all the others the increase of lateral, or rather circumferential, strength by my method of manufacture was great—indeed greater than I expected.

These guns had been made to test a principle, not as models. They would all have been too light for service except the 9-pounder. In No. VII. (Vol. II.) of the *Journal of United Service Institution*, page 323, I have given drawings representing the proportions and the method of manufacture I would recommend for large guns—to throw a ton of iron, for instance.

I will here give a drawing of an 18-pounder field and siege gun I should like to see supersede the 38-cwt. gun now used. This gun would have double the strength, would cost less originally, and, weighing only 22 cwt., the transport would require fewer horses. Only the breech-end would require the strength of the double tube; but for some purposes it would be well to have a few guns made as light as possible. In these the principle should be applied the whole length of the gun. By using wire the weight of an 18-pounder gun could with safety be reduced from 38 cwt. to 8 cwt.

Shortly after I had taken my patent for cannon (February 1855), Mr. James Longridge took one for making hydraulic presses on the same principle. To test it he had some small brass cylinders cast, one inch in diameter and one-tenth of an inch thick. Round these he coiled steel wire with a tension calculated to make each share in the work. When filled the cylinders could each contain 300 grains of the strongest sporting gunpowder. He put a certain portion of gunpowder into these, then at each end placed a copper globe, ground to fill up the aperture accurately, with the exception of a small touch-hole. The whole was then bound together by a strong wrought-iron strap, the section of which was about $2\frac{1}{2} \times 1\frac{1}{2}$ inches, and the balls keyed tight up to their seats by a jib and catbar. The powder was then exploded with results, from which he found that the same cylinder which, unsupported was bulged by 50 grains of powder, and burst by 80 grains, could bear the explosion of 200 grains when reinforced by four coils of wire, each only one thirty-third of an inch thick. The initial strain on each coil being so adjusted that each was equally strained with the greater charge. For this purpose the first coil was put on with a slight strain, the next with a greater, the third with a greater still, and so on.

Mr. Longridge next experimented with cast-iron cylinders, one inch in diameter and one-tenth inch thick, but close at one end. The other he secured much in the same way as in the brass cylinders. When filled these cylinders could hold 305 grains of powder. They were strengthened with iron-wire coiled on with the requisite increasing tension. With eight coils of No. 21 iron wire, then, it appeared that these cylinders could bear the explosion of 95 per cent. of as much gunpowder as could be put into them. To find if it was the material which gave this strength, and not the method of making each part do its work, Mr. Longridge obtained a piece of the best wrought-iron, and made a cylinder similar to the others in size of bore, but with sides twenty times as thick. This burst with a charge of 100 grains of powder. Mr. Longridge next made a three-pounder gun of a copper tube, with iron wire coiled on it. It was meant to be fired with its breech abutting against some resisting substance; but at Woolwich they fixed it with the front flange resting against a piece of timber, and, of course, blew the breech off. To test the strength of this cylinder Mr. Longridge afterwards loaded it, buried it in the earth between two strong pickets firmly driven in, and fired the charge. It showed enormous strength.

(To be continued.)

THE MAGNETISM OF SHIPS.

By F. J. EVANS, Esq., Master R.N., F.R.A.S., Superintendent of the Compass Department, Admiralty.

(Concluded from p. 41.)

In the Royal Navy, as recommended by a scientific committee of truly eminent men some years since, the system of no compensation is adopted as a general principle: but a rigid adherence to prescribed rules for preserving the compass as free from error as circumstances will permit is enforced—thus no iron is permitted within fourteen feet of it, if practicable; and a careful selection of site for each compass in every ship is made under proper supervision. It is accordingly found to result that the amount of deviation in the Royal Navy is in general small comparatively, and that no example of a deviation larger in amount, even in our iron ships, (in England) than from 25° to 28° exist, and this only in one or two exceptional cases.

The mercantile marine adopts more generally the system of adjustment, and this has led to the introduction of various patented compensating plans, differing widely from the Astronomer Royal's views, based often on no theory whatever, ending frequently in failure, and thus weakening the confidence of the seaman in the compass, and leading him to consider that the magnetism of an iron ship is so capricious as to be beyond all laws and all remedy.

These remarks may not be inappropriately closed by referring to examples of the remarkable

want of caution on the part of iron-ship constructors and those engaged in their equipment, evinced in the injudicious arrangements for the compasses given in the Liverpool Compass Committee's Reports. Among the instances quoted will be found the following: "The error in the first position of the binnacle was 101° . As the ship was going to the East Indies, the compass-adjuster objected to compensate so large an amount, and the binnacle was then placed three feet forward; here the error was reduced to two points. In another and much larger ship the compass in the first position of the binnacle deviated 14 points; on moving it a little further forward, the error was reduced to $2\frac{1}{2}$ points." These cases occurred when the original position was selected near the rudder-head of iron vessels, in which a strong attraction existed towards the stern.

It must be evident that under such circumstances of position no compass, whether compensated or otherwise, can possibly act faithfully, nor can any accurate theoretical deductions be made from such examples; nor, above all, need we be surprised at the serious consequences which too frequently result from dependence being placed on these marvellous mal-arrangements. The Liverpool Compass Committee acted wisely in the promulgation of a circular calling attention to these facts, and expressing their opinion that by attention to the circumstances under which a ship is built, and care in selecting a suitable position for the binnacle, the original error of the compass may be reduced within small limits.

Any observations on the theory of a ship's magnetism would be incomplete without reference to Mr. Airy's method of compensating forces, based as it is entirely on the laws which have been referred to, that is,—

At any place the deviation of the compass in any ship, whether wood-built or iron-built, may be accurately represented as the effect of the combination of two forces, of which one alone would produce a disturbance following the law of polar-magnet deviation, and the other alone would produce a disturbance following the law of quadrantal deviation.

Consequently, at any place the deviation of the compass may be accurately corrected by well-known mechanical methods; namely, by a magnet in the athwartship direction, fixed at a distance determined by trial, for correcting the deviation when the ship's head is north or south; by a magnet in the head-and-stern direction, also at a distance determined by trial, for correcting the deviation when the ship's head is east or west; and by a mass of unmagnetised iron, at the same level as the compass, in the athwartship line or in the head-and-stern line, according to circumstances (usually in the former), also at a distance determined by trial, for correcting the deviation when the ship's head is N.E., S.E., S.W., or N.W.

For the same ship, the mass of unmagnetised iron, if adjusted at one point, will produce its due effect at all parts of the world, without ever requiring change or adjustment. The quadrantal deviation may thus be accurately corrected without difficulty, leaving only the polar-magnet deviation uncorrected.*

Mr. Airy's later investigations have led him to consider it desirable that the magnets should be mounted in such a manner that their distance from the compass can be delicately changed, to meet the changes of polar-magnet deviation.

We may expect at no distant period that there will be an accumulation of facts from various parts, particularly from the southern hemisphere, sufficient to prove the accuracy of Mr. Airy's views of compensation under all conditions, and whether its delicate and important manipulations can be entrusted to all classes of navigators. On one point, however, mariners may be assured, that at present no other method of compensation has been brought to their notice that has been more elaborately worked out by high scientific and philosophical attainments, and that could equally stand the test of such profound mathematical analysis, as has been brought to bear on the subject by the Astronomer Royal.

* See *Philosophical Transactions* for 1853, Art. V., Discussion of the Observed Deviations of the Compass in several Ships, wood-built and iron-built, &c., with a General Table for facilitating the Examination of Compass Deviations, by G. B. Airy, Esq., Astronomer Royal.

THE MAGNETISM OF SHIPS.*

THEORETIC MAGNETIC CONDITION OF IRON SHIPS BUILT IN ENGLAND, WITH THE DIP OF THE NEEDLE FROM 68° TO 70° N., PREVIOUS TO BEING LAUNCHED, ACCORDING TO THE LATE DR. SCORESBY.

The axial line *S N* in each figure represents the direction of the dip or line of magnetic force as passing through the general centre of gravity of the material of the ship.

All below the equatorial line *E Q* shaded with firm lines has Northern polarity; all above it, shaded with dotted lines, has Southern polarity.

TASK-WORK v. DAY-WORK IN THE DOCKYARDS.

A FEW years since the system of day-work was ignored, and the public press was rampant in its censure, demanding task-work in order to satisfy the country that a fair day's work was obtained for a fair day's money. Task-work was therefore introduced, and in the course of a short space of time the most magnificent fleet that ever swam was fitted out from the Royal Dockyards; and where is the individual whose heart did not throb with delight on witnessing the departure of that fleet from Spithead in the late war with Russia? These ships were the strongest that ever floated; were built with the strictest regard to strength and economy; and the workmen employed were paid from schemes of prices requiring very nearly "double" the amount of the work done for money in the private dockyards, resulting in the fact that whilst by these prices the men of the dockyard got at the rate of 5s. 6d. per diem, those in the merchant yards, on the gun-boats and other vessels, were receiving from 9s. to 15s. Merchant builders were encouraging men of the dockyards to enter their service—making choice of them before others to work for them.

Finding job-work to the advantage of the employer, shipbuilders would have introduced it in the merchant service, but the men of the union inform us that they protested against it as oppressive in many cases, in consequence of the estimates and contracts being taken low, then underlet, and, consequently, the men ground down. Task and job-work now receive the censure of those disposed to find fault, and object to restriction, and there is a disposition for change, though it is found that whilst the people on task-work get 5s. 6d. per day as earnings, the work is done at one-third less expense than by employing the people on day-pay—at 4s. per day. Job-work is nothing more than payment of so much for building the ship, whilst task-work provides for the various jobs distinct in building. To

MAGNETIC CONDITION OF VARIOUS IRON SHIPS RESULTING FROM ACTUAL EXPERIMENT, AS DETERMINED AT LIVERPOOL BY THE COMPASS COMMITTEE, 1856-7.

NOTE.—The letters *P* and *S* denote the port and starboard lines of no deviation.

have vessels built substantially, let there be a greater number of foremen made who can watch the operation of the works, and then task-work is the best for the service. Let the Admiralty call a committee of the superintending measurers of the various dockyards together, and from our personal knowledge of them it will be found that an amount of invaluable information will be collected. It was the saying of an old master shipwright—"If you want your work done have task-work; if you don't want it done have day-work."

There is another very important matter to be considered. The master measurers of the various yards have an important trust committed to them. They are responsible for the proper discharge of the whole of the duties of the office—to see that the thousands of pounds weekly of the public money are properly expended, and the work done in a workmanlike manner; and yet their pay is but £180 per annum, whilst there are those appointed to do the secondary duty of dividing the money for payment who have salaries of between £300 and £400 a year, with others to assist at the same rate. If ever there was a mistake this is one, and we hesitate not to say, that with proper organization £20,000 per annum of the public money may be saved through the instrumentality of task-work. Give support to the master measurers, and pay them for their responsibility; and seeing that they have a very great responsibility to sustain, give them a first instead of a subordinate position. Now they can be snubbed and silenced in the face of injustice, and compelled to be dumb; give them their due importance, and justice will be secured in every respect to the country.

It may be added that if there is any doubt about the difference between men in the Dockyards and the private establishments, we know and affirm that the former are by far the best and most substantial workmen.

Mis-statements have been made in the House of Commons that will be confronted, and if His Grace the Duke of Somerset, with the noble lord

the secretary to the Admiralty, but give a trial to the preceding suggestions, economy will be secured in the public establishments, and an opportunity given for those who have been calumniated to prove themselves up to the mark. PHENIX.

TRIALS OF MOWING AND REAPING MACHINES AT WARWICK.

THE mowing machines were tried upon a piece of grass belonging to Mr. B. Dickinson, Goy Brook Farm, not far from the town of Warwick. The crop was rather light. There were three mowers in the field—Burgess and Key's, Wood's (American), and Harwood's, which we alluded to in our account of the Ipswich Show. It was soon evident that Mr. Harwood had little chance of competing with either of the other two, for his machine left patches here and there uncut altogether; and when it did cut, the lowest sweep it was capable of making left much too good a portion of the grass upon the ground. Wood's did much better; but that also left occasional patches, and could not cut uniformly, and sufficiently low, so as to secure the greatest bulk and the sweetest portion of the crop. We entertain the same opinion as we have already expressed, as regards the grass-cutting powers of this machine. The mower of mowers, at least as far as we have yet seen, is that belonging to Messrs. Burgess and Key. There is no mistake about its effective working power; it goes into the crop, no matter how laid or trampled upon, and cuts it, to speak in familiar phrase, as close and as clean as a razor. This fact was evident to every spectator in the field, many of whom closely examined the ground, and most of whom, who had any practical knowledge of such matters, expressed themselves in the highest terms as regards the power of the machine. The saving in the crop of even moderate weight and extent, when cut by a mower like the one we have briefly alluded to, would therefore nearly pay for the first cost of the machine. As a proof, moreover, of the opinion entertained by the owner of the field as to the merits of the machine, he requested Mr. Burgess to cut the remaining portion of the crop, to which he acceded; and we have since seen a copy of a letter, addressed by Mr. Dickinson to Messrs. Burgess, in which he expresses his high satisfaction at the manner in which the work was done, and gives a practical proof of his convictions being well founded, by securing for himself one of these mowers.

The reaping was upon a piece of green oats, and did not furnish any very satisfactory results as to the relative power of the machines. The crop cut belonged to Mr. Woodward, and though it was heavy and much laid in places (supposed to have been purposely trampled down to baulk one of the machines), the best reaper did its work very well. Messrs. Burgess and Key's well-known machine cut down some of it in the condition just described, about one acre and a quarter, and left the ground very clear of the green corn. The others did their work very fairly, considering all things, the nature of their construction, and the difficulty of handling so unfavourable a crop. However, it was a mere experiment, got up to amuse the visitors, more than to show the working power of the reapers. Not so as regards the mower. Everything connected with that machine was serious and earnest, as regards its work; and so well did the Society appreciate the mower, that a silver medal was awarded to it.—*Bell's Weekly Messenger*.

RIFLING LARGE CANNON.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN, — Captain Jervis, R.A., in his place in Parliament has asserted that it is impossible to rifle large cannon. I will undertake to have a sixty-eight pounder rifled, which shall throw an elongated iron or steel shot, poised on wooden wings to prevent injury to the interior of the gun, and of between two and three diameters of the bore of the gun in length, and undertake, also, to fire two such rifled cannons instantaneously by percussion, after the manner

that I fire two of my percussion blasting cartridges placed in the same line, and two or three feet apart, when blasting the monster stumps of large forest trees.

I should like to know how plates of iron four and a half inches thick could stand the simultaneous blow of two such elongated steel shot.

Your obedient servant,
J. NORTON.

Rosherville, 16th July.

BOAT-LOWERING APPARATUS.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—As the qualities and merits of mechanical contrivances can never be settled by argument, it would be useless for me again to repeat the answers I gave in my last letter to you in reply to the former objections urged against my system of lowering boats by "Nauticus," and of which his letter in your last week's impression is mainly a repetition. I then offered to show the groundlessness of such objections by at once submitting to any practical tests to disprove them, and this, too, against any other inventor or invention. Competitive trials of rival improvements under the very circumstances and cases for which they are required can be the only satisfactory solution of the efficiency of either to accomplish the desired ends, and settle their relative capabilities; and the results of such trials are the only substantial arguments on which judgment should be formed.

In order to meet theoretical objections by actual practice I devoted three years entirely to going to our different seaports and dockyards in order to prove in my own person that my invention was capable of effecting all it proposed to accomplish. Not only have I never had one accident during that time, but I now repeat that I am at any moment prepared to show how efficiently the system will work under those very positions in which "Nauticus" considers it would be useless. But more; repeated instances have occurred, as he or any one may see from my published pamphlet, of lives having been saved under just such circumstances as he describes.

With respect to pendants having broken in some of Her Majesty's ships, I myself admitted this had occurred, and I gave as the cause that rope of a character and quality different to my printed instructions had been supplied, but that this had happened with reference to the rope supplied from one yard only; but I never hinted at the invention having been neglected by the Dockyard authorities generally. Very far from it. I am fully sensible of the attention that has been paid to my instructions, the facilities that have been afforded me to carry them out, and the general excellence of the workmanship and material supplied at all the Government yards. I feel this acknowledgement the more due, because I never had a particle of patronage or official influence to help me along; and I believe that sympathy with the cause I advocated, viz., the observance of better precautions for the preservation of life at sea, had more to do with the readiness that has been shown to help me than anything else.

The "written statement" published by "Nauticus" in reference to the alleged loss of "the whole of a boat's crew" of Messrs. Greens' ship, the *Orwell*, and imputing such a catastrophe to my lowering gear, is simply an untruth; and it is to be regretted that a statement calculated to do such a serious injury, should have been anonymously published in your paper, and upon an anonymous authority. It will be quite sufficient to send to you a statement from Messrs. Green, written after a full inquiry into the circumstances on the return of the ship, and which I have also from the captain of the ship; I quote their very words—"that there was not the slightest blame attached to Clifford's lowering gear on that occasion;" and they add, moreover, "that where it has been fitted in Messrs. Greens' ships, it has given general satisfaction." I leave you, Mr. Editor, and the public, to draw your own conclusions of

the value of theoretical objections substantiated by such evidence.

And now, Sir, as "Nauticus" has referred to the subject, I must make one remark about rival inventions. In endeavouring for several years to bring before the Government and the public the almost universal disregard of life at sea, shown in the neglect of the necessary precautions in the event of emergency, I have always contended that it is the duty of the Government to make it compulsory that all ships should have on board an efficient means of lowering the boats, but that such efficiency ought to be decided after actual test and experiment under properly constituted authorities, and not left either to the option of officers in charge or owners, who would too frequently let friendship or interest influence their decisions. If in exposing the evils of the system generally in use I have shown the palpable advantages of a better one, and adduced instances of my own invention having saved lives, it has simply been because in this respect it stands alone, no other having done the same; and however I may have endeavoured to show the criminal responsibility that rested with the Government and officers in charge in failing to have such at hand, I have scrupulously avoided attacking any other inventor, holding that all had a like right to a chance of public trial to prove their practical value.

Such anonymous letters as those of "Nauticus" and others show that the attention of naval officers is at last being aroused to the consideration of a subject they have allowed to pass unheeded too long.

When any one will accept the challenge I gave in my last letter, and prove by actual working the superiority of any other plan to mine, so much the more to the public good. Till they do so I shall not forego the claims mine has established to the position that has been accorded it by the patronage it has received from different departments of the Government; and I can refer with no little satisfaction to the leading mercantile firms of London and others who have long had it in practice, and many of whom have saved lives by its use, in confirmation of what I have advanced.

Yours, &c.,

CHARLES CLIFFORD.

14th July, 1859.

THE STEAM RAM.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—I am much obliged by the insertion of my letter upon the steam ram, and for the notice you have taken of my communication, which affords me the opportunity of expressing an opinion I have long entertained—it is simply this:—

Small steam-vessels of the greatest practicable speed, and of a construction and form adapted to the service of, and armed with submarine explosive shells, would, in naval combat, prove more than a match for large ships or steam-vessels armed with any kind of cannon and projectiles at present known; and that the larger the ship or vessel so armed, the more easily could she be sunk or blown up by the small steam-vessel.

The employment of submarine explosive shells inverts, as it were, the whole system of naval tactics; for the smaller the vessel, so that she possesses speed, darker the night, more tempestuous the weather, the more easily would she accomplish her work of destruction. Not that such conditions must obtain if she be properly constructed and equipped; she would under any condition do her work in the light of day by submitting to a trifling sacrifice of damaged topsides.

I will avail myself of this opportunity to remark that the important problem of the submarine explosive shell has never been, by the proper authorities, examined; much less has it ever been, in a practicable form, solved. The sooner it is the better will it be for England—not only as it may spare her an immense outlay upon useless labour and skill, but as it may also affect her supremacy upon the ocean. I remain,

JOHN HARVEY, R.N.

Sandgate, Folkestone, July 16th, 1859.

Law Case.

COURT OF QUEEN'S BENCH, Guildhall, July 14.—
(Sittings at Nisi Prius, at Guildhall, before Lord Chief Justice Cockburn and a Special Jury.)

GRIFFITHS v. TURNER.

Mr. Bovill and Mr. Hindmarch were counsel for the plaintiff; and Mr. M. Smith and Mr. Sumner for the defendant.

Mr. Edward Griffiths, of High-street, Camberwell, confectioner, brought this action against Mr. George Turner, of Dover-road, Borough, dealer in patented articles, for an infringement of plaintiff's patent apparatus for beating the whites of eggs and other fluids. The infringement was admitted, and the question was whether the patent was not void for want of novelty. The defendant relied on a patent of Messrs. Pollitt and Eastwood for churns, and a publication of an invention by Mr. Harke, also a patentee for churns, being substantially identical with the patent of the plaintiff, and prior to it in point of time.

The trial, which commenced on the 13th, was not concluded until 4 o'clock on the 14th, when the jury found that as to Pollitt and Eastwood's patent it was the same as the plaintiff's, with this difference, that the plaintiff's had concentric axes, which, in the opinion of the jury, was an important improvement with reference to the object to which the apparatus was applied; and that as to Harke's invention it was the same in form and construction as the plaintiff's, with the difference of having flat expanded wooden beaters, whereas the plaintiff's had slight wire bars, which more readily effected the object of the apparatus.

The Lord Chief Justice said the plaintiff would have the right to raise the question whether, notwithstanding the similarity of the instruments, the novelty of the combination was not sufficient to constitute a good patent, and the defendant would have the right to raise the question whether, looking at the particular language of the specification, the points of identity found by the jury were not sufficient to invalidate the plaintiff's patent. It did not seem to him of much consequence how the verdict was entered.

Verdict for the plaintiff, with liberty to defendant to move.

Our Weekly Gossip.

A DISCUSSION was raised a few evenings since by the Earl of Airlie in the House of Lords on the arming of mail and other steamers for war purposes. In the course of the discussion the Duke of Somerset said that for many years it had been part of the contract with the companies which carried the West Indian and other mails that they should adapt their vessels to the purpose of carrying armaments. About the year 1852 a committee of military and naval officers inquired into the question, and reported that it was not expedient to attempt to fit these vessels for purposes of war; that, in fact, in doing so we diminished their utility for purposes of traffic, and only made them very inefficient for those of war. In the year 1853 there was a further inquiry by professional men, who reported that by means of a considerable expenditure some of these steam vessels might be rendered capable of carrying armaments, but that under those circumstances they would only be able to defend themselves, and could not contend with vessels of war. A suggestion had been made by Mr. Laird that some of the small steamers on the Mersey might be fitted out for the purposes of defence, and as soon the question was brought under the attention of the Board of Admiralty they sent down an officer to survey the vessels, and report how far this scheme was practicable. He did not anticipate that very much would arise from this inquiry; but, at the same time, it was desirable that we should know how far these vessels were applicable to the purposes of war. Few persons were now of opinion that these large commercial steamers could be fitted for war, and a great money expended for that purpose would be entirely thrown away; but, looking to the means of production at the command of these great companies, there was no doubt that if any sudden emergency did arise they might be made available for turning out vessels of war at short notice. The late Government had tried this to some extent by making arrangements to

build a certain number of corvettes by contract, a species of vessel which the commercial yards were peculiarly qualified to deal with, and if any sudden emergency should arise he should be inclined to deal with the matter in the same spirit. The answer, therefore, to the noble earl's question was, that the Government had considered the expediency of entering into arrangements for the arming of these large commercial steamers, but they were not disposed to re-open a question which had already been decided in 1852 on grounds which might be seen on reference to the report of the committee. The Earl of Hardwicke agreed entirely in the decision arrived at by the noble duke. Unless Parliament chose to go to the trouble of providing for the manner in which those steamers should be built it was impossible to hope that they would ever be available for war purposes, and any money spent for that purpose would be thrown away. At the same time, there was no doubt that the producing power of the mercantile navy might be safely relied on for the rapid production of war vessels on an emergency.

In reference to the letter of Capt. Harvey, R.N., which appears in another column, we may state that he has, he believes, completely succeeded in producing an engine of destruction, in which are combined easy construction with cheapness, safety when charged and when stored, facility of application in combat, with perfect freedom from danger, while the shell would be horribly destructive to a foe against whom it might be employed. A submarine explosive shell, embracing such essentials, is deposited for public inspection in the Museum at Canterbury. In the summer of 1844 Capt. Warner made an experiment off Brighton, which suggested to Capt. Harvey the importance of submarine explosive engines in naval warfare, looking to the then altered state of navigation, as compared to what it was in the days of Nelson, by the application of steam-power to nautical purposes. Under this impression he set about constructing a shell to explode under water, such shell to be brought into contact with the object of attack by being towed by a steamer of superior speed, or by spanning two shells with a buoyant line of about 100 yards length, and when so spanned, to stretch them across the course of the advancing or pursuing enemy. To this matter Capt. Harvey endeavoured more than 14 years since to gain the attention of the Government, but in vain. But we have now a neighbour who will not be restrained by antiquated notions of chivalry, or rules of legitimate modes of warfare. He well knows that the art of war is the art of strategy; and should he and his legions at any time resolve upon an invasion of our shores, and should he be before hand with us in the employment of the arm to which Captain Harvey draws attention, he could, in less than 24 hours, clear the Channel of hostile vessels, so that his troops in their passage across would meet with no interruption. It is upon the engineering and mechanical skill of England that her safety depends; for the gentlemen in the profession of arms are but too often under the dominion of fixed ideas.

Mr. T. Moy writes on the subject of steam-ship performance as follows:—"As this subject is likely to be revived at the next meeting of the British Association, allow me through your pages to suggest the following formula for obtaining a co-efficient:

$$\frac{d \times v}{p} = c.$$

d = displacement in tons;
 v = speed in feet per minute;
 p = indicated horse power."

The new French gun, of the performance of which we hear so much from Milan and from the French camp, but not from the Austrian side, cannot be an arm of the same precision as the so-called Armstrong gun, because no attempt is made to lessen the windage of it, the shot fitting not more closely than the ordinary round shot. The interior of the barrel is rifled with three, four, five, or six flat, rectangular, shallow grooves—the heavy naval guns with three, the field-gun used in Italy with six, the other, indeed the whole thing, being yet only experimental. The shell, which is of iron, is about twice and a half as long as it is broad, the greater part being cylindrical, the rear end quite flat, and the point conical. The fuse enters this point. From this iron shell projects small leaden trunnions, double in number to the grooves of the barrel, so that into each groove fit two of the little projections. These look like round leaden coins laid on the shell in two rows. They, however, are firmly fixed, being cast into holes broader at the bottom than at the surface. But a small portion of the surfaces of such projections can bear on the barrel, so that the lead must strip, or at least lose its shape. The form is exactly that which admits of least bearing surface. In Lieutenant Engstrom's

patented shells (1855) he uses round trunnions to fit into the grooves of his rifle, but then he had an object in so doing, viz., to enable him to use a decreasing twist. In the French shell all the disadvantages of the system are adopted without the advantage, for with a double row of trunnions of course the twist of the groove must be uniform.

It was a very pleasant change last Saturday, after the rumours of bloody deeds of war which have been exciting such painful interest during the last two months, to be present at the fête which was given by those interested in the proposed Palace of the People upon the site at Muswell-hill. This beautiful spot is situated to the west of the Great Northern Railway, about half-a-mile from the Wood-Green station, which is five miles from King's-cross. The total property about to be purchased by the proposed Company covers an area of 460 acres, about 150 of which are to be devoted to the purposes of the palace, and the rest will be made available to the shareholders for building and other purposes. The rise from the railway, through pleasant green fields, to the upper level on which the palace is to stand is 198 ft., and the view from the summit is extremely varied and extensive, in fact in one direction it is possible, on a clear day, to see a distance of fifty miles. Within a radius of six miles of this hill north of the Thames are situated 32 distinct towns and villages containing a million-and-a-half of inhabitants, and we understand that it is with the intention of providing a place of innocent recreation for this vast population that the Palace of the People is to be built. It was at first considered by some that such a place was not required, and that it would interfere with the ultimate success of the Crystal Palace, but it appears that such will not be the case; the erection of the Palace of the People may produce a spirit of emulation but not of competition; in fact, the presence at the fête of Mr. Bowley, the talented manager of the Crystal Palace, would sufficiently show that the interests of both will be promoted by this new undertaking. It is also an established fact that at present there is no place of public recreation of a similar nature on this side of the river. We understand that the building itself will be 1,080 ft. long by 312 ft. wide, and will be surmounted in the centre by a large dome of crystal 200 ft. span. This will be glazed as far down as the ground level so as not to intercept the view, and be used as a tropical garden. The building will also be provided with a concert-room capable of holding 10,000 people. We are led to understand from the estimates, that the total outlay will be about one-half of that invested in the Crystal Palace, so the success of the undertaking in a commercial point of view is pretty well ascertained. The summit of the hill, so soon to be a busy scene of labour, was on Saturday crowned with a large tent, under which was spread a substantial repast; the guests, to the number of 150, including many men of influence. After surveying the grounds and welcoming Lord Brougham, who it appears takes a great interest in the success of the undertaking, we had the pleasure of listening to a preliminary report, which was read by Mr. John Masterman, to which Lord Brougham replied in eloquent terms, stating that for many years he had been looked upon as the head of the educational movement, that he had often been charged with paying court to the people, but here, upon the site of the Palace of the People themselves, he would give them some good advice. He then said that all working men required relaxation, and that relaxation must be mental as well as physical; that the object which those interested in this Palace of the People had in view was the promotion of such relaxation; but to effect this three principles would be involved: it must be innocent, it must be conducted within the bounds of prudence, and it must be entirely free from a vicious tendency. He then gave a slight sketch of the manner in which this would be carried out in the Palace of the People, through the instrumentality of reading-classes, lectures, &c., and concluded by wishing every success to the undertaking.

The American aeronauts have just performed a feat worthy of being chronicled—an attempted trip from St. Louis to the city of New York. The New York letter of the *Times* gives the following account of it:—"The balloon, one of monster size, was in addition provided with revolving wheels for propelling it any desired direction, and with a metallic lifeboat suspended to the car, for use in case of falling in the water. As it turned out the precaution was a wise one. They left St. Louis about 7 o'clock in the evening of the 1st in the presence of a crowd of many thousands. At 4 o'clock in the morning of the 2nd they passed near Fort Wayne, in Indiana, and at 9 of the same morning passed near Cleveland, and over Lake Erie. In this part of their passage their speed

is reported as nearly 75 miles an hour. Up to this point they seem to have followed the course which they had marked out for themselves. The plan was to have followed the course of the Central Railroad across the State of New York and thence down the Hudson River to New York; but unfortunately they determined first to make Rochester, near Lake Ontario, and land one of their passengers. In descending to do this they fell into a hurricane strata which drove them out to sea, and obliged them for safety to make way to shore and abandon the rest of their trip. In less than 20 hours, however, they travelled 1,150 miles, and they think that they have demonstrated that for which this was an experiment—the possibility of an aerial trip across the Atlantic.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

The abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgement:—

STEAM ENGINES, &c. *None.*
 BOILERS AND THEIR FURNACES, 2774, 2803.
 ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 2775, 2779, 2796.
 SHIPS AND BOATS, including their fittings. *None.*
 CULTIVATION OF THE SOIL, including agricultural and horticultural implements and machines, 2784, 2789.
 FOOD AND BEVERAGES, including apparatus for preparing food for men and animals, 2771, 2802.
 FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 2777, 2782, 2783, 2785, 2786, 2791, 2792, 2800, 2801, 2805, 2808.
 BUILDINGS AND BUILDING MATERIALS, including sewers, drain-pipes, brick and tile machines, &c., 2781, 2795.
 LIGHTING, HEATING, AND VENTILATING, 2787, 2807.
 FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 2780, 2794, 2798, 2804.
 METALS, including apparatus for their manufacture. *None.*
 CHEMISTRY AND PHOTOGRAPHY. *None.*
 ELECTRICAL APPARATUS, 2773.
 WARFARE, 2778.
 LETTER PRESS PRINTING &c. *None.*
 MISCELLANEOUS, 2772, 2776, 2788, 2790, 2793, 2797, 2799, 2806, 2800.

2771. J. CAMERON. "Improvements in apparatus for the manufacture of sugar." Dated December 4, 1858.

This consists in constructing apparatus for curing or cleaning sugar by vacuum, with a false bottom or surface for supporting the sugar, constructed of a series of separate flat-topped bars arranged in close proximity over a chamber capable of being exhausted of air. *Patent completed.*

2772. R. LEGG. "A machine for combining the operation of compressing and cutting tobacco during the process of manufacture." Dated December 4, 1858.

This consists in a machine in which the tobacco leaf (after the damping process, when that is employed) is received into a feeding trough or box, from which it is drawn forward, and submitted to a yielding pressure by and between rollers which convey it to the mouth-piece, where it is then submitted to the action of the knife. The invention is not described apart from the drawings. *Patent completed.*

2773. L. W. FLETCHER. "Improvements in the construction of electric telegraph cables." Dated December 4, 1858.

This consists, 1, in certain modes of constructing electric telegraph cables whereby the conducting wires shall be prevented from being injuriously elongated by any elongation of the covering wires. 2. In coiling or twisting the conducting wire, or the strand of conducting wires in contrary directions, so that when the electric telegraph cable is in a state of tension the said wires may be free to elongate to a greater extent than the covering wires. 3. In weaving fibrous materials over the conducting wire previously to insulating it. 4. In weaving a tube over the insulated wire. This woven cover or tube may be made of wire-warp and a binding web of hemp, &c., or *vice versa*. 5. In covering the insulated core of electric telegraph cables with woven strips or bands of a combination of wire and fibrous material saturated or coated with india-rubber or other suitable substance. The invention is not described apart from the drawings. *Patent completed.*

2774. J. B. FISHER, J. FISHER, and J. BIRD. "An improvement in the doors and dampers of furnaces and other places where intense heat has to be resisted." Dated December 4, 1858.

This consists in forming the doors and dampers of furnaces of a single slab of fire-clay, bound with wrought or cast-iron. *Patent completed.*

2775. R. PICKERING. "Improvements in communicating signals from one part of a railway train to another." Dated December 4, 1858.

Here a flexible tube is carried along beneath the bottoms of all the carriages in the train, terminating in a whistle at a part where the engine-driver stands. This tube is in separate lengths for each carriage, provision being made for coupling the ends when the train is made up. Each carriage has a branch tube with a mouth-piece for blowing into; and each branch tube has a sub-branch and a mouth-piece and tap or valve for each compartment. *Patent completed.*

2776. E. A. SKEVIER. "Improvements in pressure and fluid level indicators." Dated December 4, 1858.

The peculiar characteristic of this apparatus is the giving of a different signal for each extreme limit, and of a third signal for the intermediate degrees of pressure or points of elevation. The invention is based upon the following principle:—Where an electric current passes along a wire in the immediate neighbourhood of a magnetic needle, the latter will be deflected from its normal position in one direction or the other, according to the direction of the electric current. The patentee has applied this principle to existing pressure and level indicators. *Patent completed.*

2777. T. SIBLEY. "Improvements in looms for weaving." Dated December 4, 1858.

This relates to those looms in which tappets are employed for working the treadles that operate the warp threads, and refers to those tappets known as "Woodcroft's patent segment tappets," more particularly single-acting tappets. The object of the invention is to facilitate the changing of such tappets. The patentee claims, 1, securing the tappet-holding plates of tappet cylinders together by bolts, so that they will not have to be disturbed when placing, removing, or re-arranging the tappets. 2, Retaining the tappets in their places by loose pins which are prevented from moving endway. *Patent completed.*

2778. A. SMITH, J. TOWNSEND, and E. W. WILLIAMS. "An improvement or improvements in breech-loading fire-arms." Dated December 4, 1858.

This relates to those breech-loading arms in which the barrel moves in a vertical plane, and consists in means for securing the barrel in its place during discharge. The inventors make a double incline or two inclines turning on axis in the body of the fire-arm, the said inclines being situated opposite to each other on the axis. On the under side of the barrel two knuckles or staples are formed with which the two inclines engage. The fastening is effected as in the ordinary construction by the motion of a handle on the axis of the inclines. They prefer to make the inclines and the handle in one solid piece. In the body of the gun two openings are formed through which the knuckles or staples on the under side of the barrel pass to engage with the inclines. The said openings are made out of the solid, and the axis on which the inclines turn is fixed on the under-side of the solid bar separating the two openings. *Patent abandoned.*

2779. J. B. A. MONNIER. "Improvements in actuating railway brakes." Dated December 4, 1858.

This consists in so arranging the apparatus for applying the brakes that the rotation of the wheels shall, when required, put on the brakes, and also so that the rotation of the wheels shall, if there is more than one brake carriage in the train, transmit the motion to all the brakes. *Patent completed.*

2780. J. TURNER. "Improvements in the construction of chairs." Dated December 4, 1858.

The inventor constructs a chair in two parts, the seat and front legs forming one part, and the back and hind legs the other part. To hold the two parts together, a screw nut is let into each of the side rails of the seat, and other screw nuts at the lower part of the back where the seat is to be fixed to it. These screw nuts are drawn together by screw bolts. In some cases he connects the two parts of a chair by fixing metal studs or buttons on one part to outer holes in metal plates fixed in the other part. *Patent abandoned.*

2781. H. T. YATES. "Improvements in the manufacture of boards or sheets, when wood sawdust is used." Dated December 4, 1858.

Here the wood sawdust is sifted into several degrees of fineness; the finer qualities are used for making the thinner sheets or boards. A quantity of powdered resin (generally about one-eighth of the weight thereof) is intimately mixed with the sawdust. In some cases particularly, for the coarser articles,

pitch is employed instead of resin. A heated metal plate is used on which a sheet of paper or woven fabric is placed, then a frame or mould according to the size and thickness of the intended sheet or board is placed on the paper. This mould is filled with the composition, then, when the mould has been lifted off, another sheet of paper or woven fabric is placed on the composition, then a hot metal plate, and so on with numerous layers one over the other, and the pile is placed within a powerful press and subjected to pressure until set. Modifications are included. *Patent completed.*

2782. J. L. NORTON. "Improvements in machines for stretching and drying fabrics, and in drying wool and other fibres." Dated December 4, 1858.

This relates to such machines as are constructed with two endless chains furnished with points to receive the selvage of the fabric, and in which such chains having received the fabric separate so as to stretch it to the desired extent, and afterwards carry it through a drying chamber. The chains are formed by stamping from wrought-iron. The chain consists of long and short links, arranged thus: two long links are placed side by side, and short ones between them; at their ends these links are held together by pins passing through the extremities of both the longer and shorter links; thus a chain is built up composed of long and short links alternately. The points to receive the selvages are held together by casting metal on to them, and the cast block so obtained has a stem which passes through holes in the long links and is secured by pins, &c. The chains traverse in guides similar to those employed heretofore. To heat the drying chamber the inventor employs a series of closed metal cylinders, to which steam is admitted. Through these cylinders a number of tubes pass, the arrangement being similar to a tubular steam-boiler. Air enters the drying chamber, or through those tubes, and thus becomes heated. From the lower part of the drying chamber a flue conducts away the air, which has been moistened and partially cooled by contact with the fabric. For drying wool and other fibres an endless fabric is placed on the chain and the fibre spread at one end of the machine uniformly on the endless fabric as it travels, and the dried fibre is discharged at the other end. *Patent abandoned.*

2783. M. HENRY. "Improvements in weaving and in looms or apparatus employed therein." (A communication.) Dated December 4, 1858.

This relates to a mode of weaving shawls, ribbons, and other fabrics, by means of which coloured threads will be interwoven only at the precise spot at which they are desired to appear. It consists in the method of action of a number of west bobbin carriers, or hooks, rods, or pins, fitted to the loom or apparatus, and carrying west bobbins or pins, and which effect in respect of the west what the jacquard effects in respect to the warp, so as to produce a west pattern in parts, and so that a very large number of small coloured wefts may be kept in the same line and in the same direction. *Patent completed.*

2784. W. E. NEWTON. "Certain improvements in grain and grass harvesting machines. (A communication.) Dated December 4, 1858.

This relates, 1, to those machines in which motion is given to a reciprocating sickle by a cam, formed of an obliquely-grooved cylinder. 2, To a guard finger of peculiar construction. The object of the invention is to compensate for the wear of the cam, and thereby ensure a perfect cutting action of the sickle, and to obtain as direct an application of the power to the sickle as may be, and with as little friction as possible. The invention also has for its object the prevention of the gumming or clogging of the sickle. The invention is not described apart from the drawings. *Patent completed.*

2785. J. PLATT. "Improvements in mules for spinning." Dated December 4, 1858.

This refers to that part of the mules used for putting up the carriage, and consists in the application of an elastic part between the source of power and the carriage. Thus, supposing a scroll employed over which the band passes, the inventor attaches the said band to the carriage by an elastic connection. *Patent abandoned.*

2786. T. R. HARDING. "Improvements in combs, gills, hackles, and similar implements used in silk, wool, and flax machinery, and in the method of making the same." Dated December 4, 1858.

This relates, 1, to the making of flat pins, and consists in cutting off the pins in the forged or ground state previous to flattening, and feeding them into a machine consisting of one or more pairs of rolls, which may be so approached to each other as to give any degree of flattening required. It also consists in flattening pins only partially, the object being to have them so flattened that they may be driven into

the stocks so as only to require one hole for each pin without requiring any mortising. It also consists in using flattened or partially flattened pins in machinery in which the pins are soldered on the stocks in lieu of the rounded pins. *Patent abandoned.*

2787. J. JOHNSON. "Improvements in the manufacture of stoves and fire-places." Dated December 6, 1858.

This relates to connecting together the cast-iron plates and other cast parts of stoves and fire-places. The patentee casts one plate or piece with a boss or projection of triangular or other form, and smaller at the top than at the base. He casts the other piece which is to be connected to it with a hole or cavity of corresponding form to the boss, so that when placed over the boss the two pieces are in their proper relative position, and the boss passes nearly but not quite through the other piece. A wrought-iron screw is placed in the mould when the boss is cast and thus becomes fixed in the boss; or it may be afterwards tapped into the boss. A washer is placed over the screw when the two pieces of metal are placed together and a nut is screwed upon it. *Patent completed.*

2788. J. G. ARNOLD. "Improvements in envelopes for letters and similar purposes." Dated December 6, 1858.

This consists, 1, in forming the piece composing the envelope from the sheet or roll so as to leave the end of the sheet, which is made wider than the proposed length of the envelope, in a shape such that the next piece shall be cut off without any or with but little waste of material. 2, In making the adhering parts closing the sides or ends to consist of narrow folds that shall come inside between the face and back when the envelope is folded, leaving the back whole and smooth. *Patent completed.*

2789. B. NICOLL. "Improvements in agricultural machinery for all kinds of crops, chaff, turnip, and other root-cutting, and for the purposes of hay-making, and rubbing corn and seed from the stalks (instead of threshing)." Dated December 6, 1858.

This consists of a framework running upon wheels having a row of cutters of peculiar form, each cutter working on a joint. Attached to the framework are endless canvasses which, by a mechanical contrivance, convey the crops at the time of cutting to any required position. *Patent abandoned.*

2790. J. and F. MUIR. "Improvements in ornamental or colour printing." Dated December 6, 1858.

According to this process, supposing there to be five colours in the design, the first two are printed by corresponding blocks as usual. The other three colours are put on from a single sieve or colour box, that is to say, from a sieve on which the three several colours to be printed are laid in stripes at pre-determined positions. In this way as the block is laid upon the sieve it takes up the three colours on the pre-determined portions of the figure, and when applied to the surface to be printed, deposits its three several colours so as to form actual integral or detail portions of the pattern. There are modifications included. *Patent abandoned.*

2791. G. SKELL. "Improvements in machinery or apparatus for cutting woollen fabrics." Dated December 6, 1858.

In the "perpetual cutting machine" the patentee constructs and arranges the framework so as to allow of an additional cutting cylinder, by which he is enabled to make two cuts at one and the same time. *Patent completed.*

2792. J. DAWSON. "Improvements in machinery or apparatus for raising the nap on woollen cloths." Dated December 6, 1858.

This consists in passing the fabric over an arrangement of rollers in connection with the raising cylinders. The apparatus is self-acting. *Patent completed.*

2793. D. B. WHITE. "Improvements in indicating gauges." Dated December 6, 1858.

This consists in the use of a syphon or bent tube containing a short column of mercury, disposed so as to balance a longer column of water, or other fluid lighter than mercury, the lengths varying according to their relative specific gravities. The apparatus is intended to be applied in the "waste" of a ship, or similar situation, the tube containing the longer column being continued upwards into the cabin, so that an increase in the depth of the fluid to be gauged may be indicated by the disturbance of the equilibrium which before existed, and the consequent movement of the upper surface of the lighter fluid, the amount of which may be observed upon a scale contiguous to such surface. The apparatus may also be used to indicate the existence of fire, or of an increased temperature at a distance above or apart from its actual locality. *Patent completed.*

2794. R. A. BROOMAN. "Improvements in the

manufacture of gloves." (A communication.) Dated December 6, 1858.

This consists in cutting out the main piece of the glove by machinery of such form that by turning over two projecting side-pieces they will form the fore-finger and little finger, and in then cutting out and sewing to the main piece, additional pieces to form the backs of the middle fingers, and part of the back of the glove, another piece to form the thumb, and another to form the wrist piece. *Patent completed.*

2796. F. W. FLETCHER. "Improvements in bolts for securing doors, and for other similar purposes." Dated December 6, 1858.

This consists in, and the patentee claims, the adaptation of excentric motion in any form whatsoever to all bolts for securing doors, and for other similar purposes. *Patent completed.*

2796. E. W. SCALE. "Improvements in railway and other brakes." Dated December 6, 1858.

This consists in the application of a spiral worm or screw fixed on the axle of the wheel to be operated on, and which may be made to lock the wheels of adjacent plain angles. *Patent abandoned.*

2797. J. E. BORD. "Improvements in the construction of taps, valves, cocks, spigots, or other apparatus or instruments for gauging or for drawing off the liquid or fluid contents of any cask, butt, vat, barrel, or other vessel." Dated December 7, 1858.

The patentee constructs a tap, valve, or cock, so as to cause it to indicate, whether the vessel containing the fluid be full or otherwise, and always exhibiting during the progress of consumption the progressive decrease, and he, therefore, attaches to any valve, tap, or cock a hollow tube of glass or other material, such tube to be in connection with the liquid to be gauged. The tap, &c., is to be so shaped by means of a bent or curved shank, that, on being placed in the vessel, it will descend into the lowest part thereof, the opposite end or external aperture of the tap to be the longest, so as to afford the advantages and combine the principles of the syphon. *Patent completed.*

2798. W. A. GILBER. "An improved portable bath." (A communication.) Dated Dec. 7, 1858.

The lower part of the bath is here composed of two iron or wooden frames, filled in with sheet zinc, the two ends being composed of similar frames and sheet zinc. The upper edge is made of round iron rods, which are connected in the middle to the head frames by iron collars. The extremities of these rods are curved and provided on each side with small pins or bolts, which are introduced into holes made in the uprights on each side. The sides of the bath are filled in with moveable sheet zinc, or with a metal trellis. When the form of the bath is obtained, the inventor places in it a bag or cover of india-rubber so as to fit the interior of the bath framework, and the edges of the bag are brought down and secured to the outer sides by springs and knobs. A tap fitted to a pipe passing through the india-rubber bag serves for letting off the water. *Patent abandoned.*

2799. C. WILLIAMS and W. ELLISON. "A new mode or method of securing and liberating the corks and stoppers of bottles." Dated December 7, 1858.

This consists in passing a pin through the neck of the bottle, and also through the cork or stopper. *Patent abandoned.*

2800. J. WHITELEY and T. KITCHENMAN. "Improvements in press plates or apparatus employed in hotpressing woven fabrics." Dated December 7, 1858.

This consists in forming a passage running first along with and near to the edge of the plate, and then continuing at a suitable distance further from the edges of the plate, and so on in a spiral like direction, each circumrevolution approaching nearer to the middle of the plate in a suitable ratio; it is then returned between the passages and continued to the outer edge of the plate again. By this method the inventor can so adjust the distances respectively of the passages as to obtain and maintain a more equal effect upon the fabrics. *Patent abandoned.*

2801. W. MADDERS and J. WADDINGTON. "Improvements in machinery or apparatus for embroidering woven fabrics." Dated December 7, 1858.

Here the inventors make the holes of different sizes according to the required design, by fixing two or more stops or catches on the frame of the machine, so as to stop the carriage at any stated point, or to regulate the distance it must move, and thus also regulate the distance the stilettoes must pierce the fabric. The stilettoes being of a conical shape, it is evident the farther they are forced through the fabric, the larger the holes will be, and vice versa. *Patent abandoned.*

2802. J. J. HARRIS. "Improvements in apparatus for refrigerating and regulating the temperature in worts and beer, which may be also employed as condensers in distilling." Dated December 7, 1858.

This consists in fitting in a suitable vessel through which the wort or beer is to flow, an apparatus consisting of a series of narrow hollow chambers or rows of pipes placed upright, and so connected together that water shall flow through them, and from one chamber or row of pipes into the next, and so on through the entire series. *Patent abandoned.*

2803. J. G. E. LARNED. "Improvements in the construction and arrangements of the boilers and working parts of steam fire-engines, part of which is applicable to engines for other purposes." Dated December 7, 1858.

This consists in constructing a boiler with sets or pairs of vertical tubes arranged annularly, the outer tube being in size in respect to the inner tube about as $2\frac{1}{2}$ inches to $1\frac{1}{2}$, and the annular space between such tubes being occupied by water. The inner tube is an air tube, and through it the air passes, and also round about the outer tubes; the fire is thus brought in contact with both sides or surfaces of the water. The furnace is also composed of tubes set close together, and opening at bottom into a ring-shaped water bottom and into the steam drum above. This construction of boiler can be applied to engines of various kinds. The invention further consists in the combination and arrangement of the working parts of the machinery for transmitting power from the cylinders through an intermediate shaft to the driving wheels, and the combination of such intermediate shaft with any suitable hydraulic apparatus, whether a rotary pump centred on such shaft, or a reciprocating pump operated by cranks on such shaft, which in such case becomes a crank shaft or axle, and also serves for steering the carriage. *Patent abandoned.*

2804. J. V. SCARBOROUGH. "Improvements in apparatus for the manufacture of boots and shoes." Dated December 7, 1858.

This relates to boots and shoes having soles and heels of gutta-percha. The invention consists in moulding the sole and heel of the boot or shoe so as not to require any subsequent trimming. *Patent completed.*

2805. J. HASLAM and J. LUTENER. "Improvements in healds used in looms and dressing frames." Dated December 7, 1858.

This relates to metal healds for weaving, and also to the application of healds composed of metal to dressing frames used in preparing yarns for the loom. It consists in the use of several flat thin strips of metal, having two holes in their flat sides, one at or near the top, and the other at or near the middle of the strip. The top hole admits of the passage of a wire which suspends the strips side by side in a row, whilst the middle hole is for the warp to pass through, which it does sideways, the hole being made at right angles to the direction of such threads. The second strips are kept from moving forward or backward at their lower ends by a wire placed on either side of them at or near their lower extremities, whilst at the same time the metal strips or healds are free to be adjusted laterally. In respect to dressing-frames the invention consists in the substitution of metal healds for those hitherto used. *Patent abandoned.*

2806. W. BURNES. "Improvements in pumping and forcing liquids." Dated December 7, 1858.

This consists in combining with machines used for pumping liquids apparatus to render the flow of the liquid uniform, notwithstanding the intermittent action of the pumping or forcing machines. For this purpose the liquid as it passes from the pumping machine is caused to enter a cylinder containing a piston of large area, and having guides to insure its rising and falling truly within the cylinder. This piston is heavily weighted. The pipe for conducting the liquid away is connected directly with the cylinder, and while the pumping is going on a uniform flow is maintained in the pipe, the rise and fall of the weighted piston compensating for the want of uniformity in the action of the pumping machine. *Patent completed.*

2807. S. W. PUGH. "Improvements in obtaining and purifying naphtha, paraffine, and other oils, and also spirits." Dated December 7, 1858.

In obtaining paraffine oil the invention consists in operating upon bituminous coals when they are mixed with charcoal made from gas, pitch, and blood, chalk, lime, or other earthy matters; also any of the oxides of iron or other metallic carbonates or hydrates. The coal, &c., is to be placed in retorts, and operated upon by heat according to the method of conducting destructive distillation. The paraffine oil thus obtained is purified in the following manner:—The oil is placed in an iron vessel coated with zinc, and treated with from 10 to 30 per cent. of sulphuric acid, and the whole well stirred. When it has well settled, the oil is drawn off into another iron vessel and treated with a solution of caustic alkali, caustic lime,

and chalk, and the whole well stirred to neutralise the acid. The oil is then drawn off into another vessel and bituminous charcoal, or peat charcoal, chalk, or lime and water containing oxide of iron is added in the proportion of from 6 to 10 gallons of this mixture to every 100 gallons of the oil; steam heat is then applied and the whole boiled for four or six hours, after which the oil is well washed with a strong solution of chloride of sodium, or a strong natural brine, then distilled in an improved apparatus in which it is proposed to employ three cylinders or stills placed side by side, and fitted in a manner which is not intelligibly described apart from the drawings. *Patent abandoned.*

2808. J. FERRABEE and F. H. ENGLAND. "Improvements applicable to machinery for carding, scribbling, and condensing wool and other fibrous substances." Dated December 7, 1858.

Here the doffers of condensers and carding and scribbling engines are covered with wire card in the same way as ordinary doffers, and by means of a certain tool the card surface is divided into the requisite number of rings by depressing annular portions of the wire surface and thereby forming a series of grooves; the wire so depressed may be retained by a series of bands of leather if found desirable. By this means perfect uniformity in the rings is secured, and the risk of their shifting and getting irregular when being ground is obviated, and a more even sliver is produced. The rubbing rolls of condensers are constructed by threading a number of rings of vulcanised india-rubber or leather on a turned hollow iron, and are received at the ends by washers. For grinding the doffer cylinder in its place the patentees construct a traversing grinder and mount it in bearings fixed on the framework of the machine so as to render the removal of any portion of the machinery unnecessary when grinding the doffer. In feeding scribbling or carding engines they take the roping from the traversing feeder by means of a roll with an endless belt running above it which delivers the roping or sliver to the feed rolls. To obtain such a distribution of the wool or staple as will ensure uniformity of sliver they apply apparatus for laying the fleeco (as it is stripped from the doffer of the scribbler or carder) in layers one above the other to any required thickness upon an endless band or table, and thus to form a continuous sheet or vat which will be fed into the succeeding machine continuously at right angles, or any other angle, to the feed rolls of such engine. *Patent completed.*

2809. M. A. F. MENNONS. "An improved apparatus for ascertaining and registering the work of certain kinds of lever balances." (A communication.) Dated December 7, 1858.

This consists in a registering apparatus to be used in combination with the ordinary steelyards or plate and lever balances, known on the continent as "Bascules à Romaine," the work of which is, by the aid of this arrangement, ascertained and printed in figures corresponding to the weight of the charge. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated June 9, 1859.

1402. W. Burness. Improvements in steam-culture machinery, part of which is applicable to steam cartage and other purposes.

Dated June 16, 1859.

1450. T. W. Jones. Stereoscopic glasses for single pictures.

Dated June 18, 1859.

1472. J. Firth and J. Crabtree. Improvements in the manufacture of carpets.

Dated June 21, 1859.

1494. L. D. Owen. Improvements in machinery for manufacturing bolts and nails. A communication.

Dated June 27, 1859.

1532. R. Dick. Keeping accounts current in printed form, for addressing cards, circulars, papers, and periodicals of all kinds, with great rapidity, by the aid of a very simple machine, which is a constituent part of this invention.

Dated June 28, 1859.

1539. W. E. Newton. An improvement in variable cut-off gear for producing expansion in steam and other motive engines. A communication.

1541. J. M. J. Baillie. A new process for tanning hides and skins. A communication.

Dated June 29, 1859.

1542. J. Nash. An improved disengaging block.
1543. G. Hall, jun. Improvements in reaping machines.

1544. A. McDougall. Improvements in the preparation of disinfecting and antiseptic substances.

1547. W. Wilkinson and D. White. Improvements in apparatuses for holding, regulating, compressing and burning gas, and other gaseous fluids, part of which apply to the holding of liquids.

1548. I. Tirebuck. Improved machinery for printing from engraved plates.

1549. W. J. T. Williamson. Improvements in gas burners.

1550. G. Chapman. Improvements in knitting machines.

1551. J. J. Griffin. Improvements in gas furnaces suitable for fusing refractory metals.

1552. G. Baker. Improvements in the manufacture of metallic lattice or trellis work. A communication.

Dated June 30, 1859.

1553. E. Francis. Apparatus for facilitating the "making up" or the packing of sugar, and other articles of grocery and other substances.

1555. R. Kay, J. Manock, J. Whittaker, and T. Booth. Improvements in machinery for slubbing, roving, spinning, and doubling cotton, and other fibrous materials.

1556. W. Bestwick. Improvements in crinoline-steel for ladies' dresses, skirts, and other similar purposes.

1557. R. A. Brooman. Improvements in lithographic and chromolithographic presses. A communication.

1558. L. Boigeol. Improved machinery for winding and twisting fibrous materials.

1559. T. Bell. Improvements in the manufacture of manure.

1562. J. A. Wilkinson. Improvements in printing presses, and apparatus connected therewith.

1563. W. Summerscales, son., and J. Summerscales. An improved wringing and mangling machine.

1564. J. Bernard. Improvements in uniting certain parts of boots and shoes, and in the means employed therein.

Dated July 1, 1859.

1565. J. R. Beard. Improvements in the manufacture of artificial whalebone, applicable to umbrellas, parasols, stays, hats, bonnets, reeds, crinolines, and other similar purposes.

1566. A. Jones. Improvements in machinery or apparatus for drawing-in, twisting, or looming textile materials.

1567. B. Standen. Improvements in the deodorizing and separation of fecal and putrescent organic matters, in the preparation or manufacture therefrom of a portable artificial manure or fertilising compound, and in apparatus to be employed in such preparation or manufacture.

1568. A. Carron. An improved loom for the manufacture of silk and other velvet. A communication.

1569. N. Ardaseer. An improved method of making steam-boilers.

1570. J. B. Howell. Improvements in the treatment of iron.

1571. E. W. Carter. Improvements in machinery or apparatus for sewing.

1572. E. A. Wood and M. D. Rogers. Improved apparatus for raising and lowering boats.

1573. S. Fisher. Improvements in ordnance and projectiles.

1574. R. Royds and A. Harcourt. An improved composition for protecting the bottoms of ships and other structures of iron.

1575. W. Biddle. Improvements in advertisement show cards or boards.

1576. W. E. Kenworthy. Improvement in purifying gas, and saving of lime in the said purifying.

1577. M. Bogg. Improvements in washing machines.

Dated July 2, 1859.

1578. C. H. Pennycook. Improvements in ventilators and ventilating flue or chimney tops.

1579. R. W. Morville. Improvements in mechanism, or arrangements for suspending and securing window shades. A communication.

1580. T. J. Hart. Improvements in breech-loading fire-arms.

1581. C. G. Guy, J. Brough, and R. Cotton. An improved upright steam boiler.

1582. E. Fourmaux, jun. A new weaving-loom.

1583. C. H. G. Williams. Improvements in dyeing fabrics and yarns.

1584. H. Hirsch. Improvements in screw propellers.

1585. H. Harris. An improved method of connecting together the parts of which bedsteads and other furniture are composed.

Dated July 4, 1859.

1586. J. Simon. A composition named seidelite, a kind of paste which becomes as hard as stone, is unchangeable by the air, and being proof against the action of acids, may replace lead and other substances for various uses.

1587. J. Hollingworth. Improvements in machinery or apparatus for the manufacture of paper.

1588. R. Lane. Improvements in mills for grinding grain and other materials.

1590. R. A. Brooman. An improved hemmer, or apparatus to be used in connection with sewing machines, for turning over and presenting the edge of the material to be hemmed properly to the needle. A communication.

1591. R. A. Brooman. A cementing powder or mixture, and process for cementing, converting, refining, strengthening, and steelifying iron. A communication.

1592. A. V. Newton. An improvement in the process of, and improved apparatus for, separating metals from their ores. A communication.

Dated July 5, 1859.

1593. J. McIntosh. Improvements in the manufacture of leather driving belts.

1594. W. Knapp and A. Aitchison. Improvements in the manufacture of gas.

1597. W. E. Newton. Improved apparatus for moving iron or other metals while the same is in process of manufacture at the rolls. A communication.

1599. J. Watkins and J. Pugh. Improvements in lubricating wheels.

Dated July 6, 1859.

1601. J. Luis. An apparatus for washing wool, manufactured or not, and all other matters. A communication.

1603. J. Horton. A new or improved gas-meter.

1605. S. B. Haskard. Improvements in the manufacture of hook guides used in machines for the making of lace or other fabrics.

1607. L. Schwartzkopf and F. C. Philippon. Improvements in steam hammers, and in machines for cutting files, and for planing and grooving iron, stone and other substances.

1609. J. T. Edmonds. Improvements in winnowing or corn cleaning machines, parts of which are applicable for other screening or sifting purposes.

Dated July 7, 1859.

1613. J. Knowelden and D. Edwards. Improvements in hydraulic engines and pumps, and the employment of apparatus for applying motive power.

1615. Sir F. C. Knowles, Bart. Improvements in making iron castings.

1617. W. Robinson. Improvements in cask washing machines.

PATENT APPLIED FOR WITH COMPLETE SPECIFICATION.

1621. W. Wait. Manufacturing bonnets, hats, and other articles, partly or entirely from the leaves of the palm tree or other flat or thin material. *Dated July 8, 1859.*

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

(From the London Gazette, July 19, 1859.)

588. R. Leake and M. Sykes. Furnaces.
595. J. Aspinall. Evaporating in vacuo.
601. A. Booth and A. Booth, jun. Tags for laces.
605. J. N. Ryder. Preserving fruits.
612. J. R. Nicholson. Needles.
616. J. Cooke. Giving signals.
626. R. Hellard. Reaping and mowing.
627. S. Wheatcroft. Goffering machines.
629. F. Clarke. Preparing peat.
631. J. Cunliffe, F. Piggott, and G. Mallinson. Woven fabrics.
636. J. Thornton. Bricks, tiles, &c.
640. R. Waller. Joining leather.
648. J. S. Dawes. Collecting night soil.
649. W. Langton. Keys and wood fastenings.
650. C. Desurmont and C. Goudeau. Looms.
663. J. Fuller. Churns.
673. C. Garnett. Ginning cotton.
681. A. Warner and W. H. Tooth. Iron.

700. J. W. Hart. Destroying insects. A communication.

709. W. Hudson and C. Catlow. Looms.

733. C. A. Watkins. Brushes.

754. H. Rigby. Motive power.

758. W. E. Newton. Ovens. A communication.

789. H. Moss and T. West. Cutting leather, &c.

812. A. V. Newton. Furnaces. A communication.

830. A. Paget. Looped fabrics.

893. J. Martin. Bonnet fronts.

911. D. Dolg. Gas lamps. A communication.

1014. C. Mansel. Travelling case.

1086. J. Morison and J. Morison, jun. Looms.

1142. T. Jones. Heating and ventilating.

1213. H. Newman. Artificial teeth.

1287. J. Harmer. Gas-meters. Partly a communication.

1300. W. H. Graveley. Aerating sea water; cooking and baking.

1347. A. Suter. Furniture castor.

1387. P. Salmon. Valves.

1480. R. Laming. Purifying gas.

1493. A. Parkes. Cylinders and tubes.

1494. L. D. Owen. Bolts and nails. A communication.

1541. J. M. J. Baillie. Tanning. A communication.

1584. H. Hirsch. Screw propellers.

1587. J. Hollingworth. Paper.

1605. S. D. Haskard. Hook guides.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed July 13, 1859.

120. J. Barrans.

Sealed July 15, 1859.

128. J. Eccles.	245. T. Hartshorne.
143. R. G. Salter.	252. G. F. Bradbury and J. J. King.
144. G. and J. Collier.	258. W. Robertson.
149. G. Hamilton.	301. S. Teame.
151. C. D. Archibald.	336. T. R. Ayerst.
152. R. A. Brooman.	496. S. Russell.
156. W. Trotter.	511. T. C. & G. J. Hinde.
160. P. A. Sparre.	556. E. Newton.
162. E. T. Hughes.	986. C. Batty.
164. E. Stevens.	1004. J. Davies.
166. W. J. Poupard.	1009. G. Roberts and J. Bridges.
171. H. Hilliard and T. Chapman.	1043. H. Altman.
172. A. Lindo.	1160. F. V. Hadlow.
176. S. Phillips.	1167. W. F. Nuthall.
189. R. Howell and R. J. Wilder.	

Sealed July 19, 1859.

161. T. Clarke.	216. J. Fowler, jun., H. Burton, D. Greig, and J. Head.
163. J. Whitehead.	276. J. Robertson.
179. J. Bent.	281. L. Rigolier.
185. L. Le Prince.	328. J. Honeyman.
194. J. H. Hume.	432. A. V. Newton.
197. J. Newman.	926. R. Coleman.
206. T. W. Rammell.	
208. H. Barter.	

PATENTS ON WHICH THE THIRD YEAR'S STAMP DUTY HAS BEEN PAID.

1660. W. and J. Clibran.	1701. J. L. Crockett.
1670. H. Turner.	1705. J. L. Crockett.
1674. T. Duncan.	1758. G. Collier and J. and J. W. Crossley.
1683. J. Cartwright.	1767. W. Wood.
1684. G. Jacque.	

LIST OF SPECIFICATIONS, &c.,

Published during the week ending July 16, 1859.

NOTE.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office.

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, JULY 29, 1859.

THE NEW COINAGE.

It is with a feeling of proud gratification that we observe set down as an item in the just published Miscellaneous Civil Estimates, Branch VII, the sum of £50,000 for a new Copper Coinage. It will be within the remembrance of our readers that this journal has for months past been urging the Government of the day to commence a reform of the inferior metallic currency of the kingdom, which has become so deteriorated by wear and tear and ill-usage as to be positively a disgrace to the community amongst whom it circulates. Our exertions have evidently been effective in the quarter where it was intended they should tell, and we record the fact with much pleasure. Fifty thousand pounds represents the purchase money of something like five hundred tons of copper, and these converted into coin would give an enormous number of individual pieces—say one hundred millions of the different denominations. This is a fair instalment, therefore, for a commencement; but we shall expect the vote of £50,000 to be an annual one for several years to come, if the reform is to be made complete.

No doubt there will be a considerable diminution in the *weight* of the new coins as compared with those now in use—at least there *ought* to be—and if instead of "Copper," "Bronze" might be read in the estimate, that also would be an improvement. However, with the Mint will rest probably the questions of size, weight, impression, and material, and that establishment will, we should think, know how to answer them.

THE STEEL MANUFACTURE REVOLUTIONIZED.

We shall not, we believe, exceed the truth in saying that the steel manufacture of this and other countries is on the point of being revolutionized. More than six months since we announced the arrival in this country of the patentee of an important American invention having the improvement of that manufacture for its object; but, notwithstanding the successful establishment of the invention in America, we deemed it prudent to defer noticing the fact with much prominence until a course of actual experiments in our own country had dispelled the doubt which, not without reason, we always feel when novelties of great pretension reach us from the other side of the Atlantic. That course of experiments has now, however, been proceeded with, and the results obtained are so extraordinary, and so momentous, that we cannot longer delay to apprise the public of them. As the savings arising from the new process will, in all probability, in the course of a very short time, be reckoned by millions of pounds sterling, we are not surprised to find that funds amounting to hundreds of thousands of pounds are already being subscribed for the purchase and carrying out of the invention.

The impurities with which Mr. Bessemer, as he has lately informed us, has experienced the greatest difficulty, and those which so long retarded the progress of his remarkable invention, were sulphur and phosphorus; and, curiously

enough, sulphur and phosphorus are precisely those impurities which Mr. Farrar, the inventor of this much more remarkable process, has more especially aimed at removing throughout his proceedings—with how much success we have already implied. Among the specialities of the new process are, first, economy of time in the manufacture by direct conversion of the iron in the crucible in three hours, doing away entirely with the tedious process of cementation, which takes from ten to twenty days. Secondly, from the same irons as are used under the old method, the inventor produces a superior steel of a more uniform character, possessing more tenacity and ductility; and from any given quantity of iron the *same quantity* of any required grade of steel, there being no loss in the melting. Thirdly, he purifies iron from all foreign substances by means of chemicals, and thus makes available for good cast steel a lower grade of iron than can be used in any known method. Fourthly, the cost of producing any kind of steel will be simply the cost of the bar-iron used, added to which must be the same expense as is now attendant upon producing it from "blister-steel," i.e., melting, hammering, rolling, &c. Fifthly, the process has also the great advantage of enabling parties to make malleable castings from ordinary wrought iron, or wrought iron scrap, a mode of manufacture which is peculiarly adapted for railway carriage wheels, and other castings requiring great strength, both tensile and other. This material is also adapted for gas and water pipe couplings, for which annealed cast iron castings are now used, and possesses infinitely more strength; it is likewise suitable for light ordnance, and any castings under 30 cwt. The patentee does not claim to make the best steel out of poor irons. The two great enemies of iron are, as we have intimated, sulphur and phosphorus, which, from the chemicals used, pass off in a nascent state.

The Damascus Steel and Iron Company of New York are now making from three to six tons of best cast steel per day out of American iron by this process, producing finished bar-steel at a cost not over £28 a ton of a quality equal to that made here out of the best brands, costing in iron bar £30 to £36 a ton. From an iron puddled by the Damascus Company direct from the ore, and by Anthracite coal, they are producing a steel sufficiently good for the best machinery steel, and saws, &c. The iron costs not more than £8 a ton, and, when manufactured by this process, not more than £20 a ton.

It is said that good steel cannot be made of common iron; nor can that be done, unless the iron is first purified of foreign substances, and thereby brought up to a better grade of iron, and better adapted for steel purposes. There are some irons in which it is impossible to reach all the impurities, viz., those containing much arsenic; with these the method would fail; but it is a fact, that for all second and third class steels there is plenty of English iron, and the second and third grades of Swedish iron are good enough for the very best steel.

Files, and many other descriptions of articles made from steel manufactured under the new process, are already in the market, and are producing no little excitement in Sheffield and other places. The reduction in the price of the steel thus made is so great that the "consumers" of steel are making numerous and increased applications for it daily; so that the demand is at present much greater than the supply that can be kept up. Vastly enlarged arrangements are, however, in contemplation. We will add but one testimonial only to the quality of the new and cheap steel. The proprietor of a very large manufacturing establish-

ment, in a letter now before us, says:—"We have tried some of the steel made here by 'Mr. F——' for gun-barrel boring, which is a 'very severe test for steel, and it has proved 'superior to anything we ever had, for which 'our price is £65 per ton.' Under the new process the best steel can be produced for less than £28 per ton."

THE LAYING OF SUBMARINE TELEGRAPH CABLES.

Of all the difficulties which beset the establishment of long submarine telegraph lines the greatest are those experienced in the submergence of the cable. We have all heard the tale of the repeated attempts to lay the Atlantic cable, and of the constant risk and fear of failure under which it was at last deposited. The knowledge of these facts urges us to ask why it is that no step has been taken towards the trial of a plan which has been fully explained in our pages—which was designed by an esteemed naval officer—which removes most, if not all, of the difficulties hitherto experienced—and which has been the subject of the repeated commendation of nautical men and engineers? We refer to Captain J. H. Selwyn's patented method of employing large drums or cylinders floating on the water and carrying the cable. Hitherto we have heard no objection offered to the advantages which he claims for it. If its novelty be an objection, we may say farewell to all possible improvement. Nothing can be more simple or, as he shows, less expensive; and the Atlantic Telegraph Company, or their contractors, would perhaps do well to give the principle a fair trial before reverting to means which have so often failed. With whatever modifications it may be adopted, there are fundamental errors in the process of paying out coils of cable which no system of brakes can do other than aggravate, and there is also the risk of a gale during the operation, for which no process of laying, save that of Captain Selwyn, provides in any adequate way. The danger to the crew—no small consideration—is in his plan entirely obviated. Further, while the Admiralty might be disposed to assist in a mode which only requires the services of steamers in towing, they would certainly refuse such aid if involving so large an expenditure as that which was necessary for the Agamemnon's fittings and repairs (£40,000 sterling), and which—or some sum proportioned to the size and weight of the new cable—would otherwise have to be borne by the contractors, and eventually by the shareholders.

Some new means must also be adopted for the raising of the old cable, for while no great length has ever been recovered in the various attempts made for that purpose, which have always resulted in breakage, even supposing it were possible to do it, the time necessarily employed with a steamer would be so great as to do away with all hope of a profit from the operation. The cylinders seem in this direction, as well as in the laying, to offer probabilities of success which at least justify a fair trial. The drum, it is evident, in the case of raising, plays the part of a large capstain or winch, winding up the cable by the power applied to the paddles on a cylinder whose diameter is fifty feet, and therefore it will have far more chance of success, and occupy far less time than a steam-engine or other mechanical apparatus placed on a platform (the ship's deck), which is liable to sudden raising and lowering by the pitching of the ship, the engine-power being exerted irrespective of such motion, or the consequent strain on the cable. The idea of under-running by means of such a machine seems to us also a feasible one, at least for the three or four hun-

dred miles of shoal-water near the coasts of Ireland and Newfoundland respectively; and it is possible that the whole fault might be discovered there, thus superseding the necessity for raising the deep portion at all.

To the Government, also, who have shown their intention to lay a submarine cable to Gibraltar, we would suggest that the question is a national one, and well worthy an attempt at solution by the means which, without any great extra expense, are at their disposal, before risking the large sum which has been voted for the cable on an attempt either by themselves or through contractors, at laying it from ships.

Indeed, it is difficult to understand how, in the cases of very large sums such as those here involved, any contractor can be found to risk the loss, in the present state of our knowledge of the difficulties attendant on deep-water laying. And how do the contractors show that in the event of their losing in laying a cable like the Atlantic, which costs say £300,000, their estate would afterwards be capable of paying a fine, or even repaying the sum advanced to carry on the work? Say the contractor fails—is that any satisfaction to the shareholders who want the interest of their money, or to the public who want the communication?

In conclusion, the whole subject deserves and should receive most careful consideration before next year, if any attempt is then to be made to revive what can never be allowed to remain dormant, since it has been proved practicable, viz., an electric communication with America, and no elucidation will be valuable which has not a due admixture of Practice combined with Theory. The laying of a cable is an operation which naval officers may be justly expected to manage more efficiently than landmen, and we hope the experience of such men as Captain Preedy and others will be made available in future undertakings.

RIFLED GUNS FOR THE NAVY.

THE article on rifled guns for the navy which we last week published has not been without result. The unprofessional press helped to gain increased attention for our remarks, and Lord Lyndhurst patriotically availed himself of the first succeeding opportunity afforded him by his place in the upper house of Parliament, by questioning the first lord of the Admiralty upon the subject. "The question I have to put to the noble Duke (of Somerset) is this," said he, "whether he is aware that the French are arming their fleet on the other side of the Channel with rifled cannon? I put this question because from the reports I have heard it would appear that the rifled cannon we are preparing will not extend to above 100 in the present year and 200 in the following year, whereas it is said the French rifled cannon are manufactured with such rapidity that they will be able to arm their fleet in that mode long before we can make use, to any extent, of the rifled cannon of Sir W. Armstrong." The reply given to this most serious inquiry was, we regret to say, calculated to remind us of the accustomed hauteur of noble functionaries, rather than to give us any kind of confidence in our armaments. The reports of the Duke of Somerset's answer to Lord Lyndhurst vary somewhat in the various morning papers, but the tenor of the whole is the same. We extract it as follows from the *Times*:—"He [the noble Duke] had only to say that of course he had heard the report, though that report was not based on any authentic information in his possession, that some rifled cannon had been prepared in the arsenals of France. He was aware also that although we had very many improved cannon in the course of manufacture

"our cannon would not be, according to our system of manufacture, ready for many months to come. But that was not the whole matter. There were many questions connected with the subject to which the inquiry of the noble and learned lord referred. He did not, however, think it desirable that he should now enter into a discussion of the questions connected with the improvement of cannon, which were now under the consideration of the department to which they properly belonged. He therefore must decline to follow the noble and learned lord into that discussion, to show what we had done in that way in answer to what the noble and learned lord imagined the French had done."

Now, if this is to be taken as an example of the manner in which questions of great public moment—not to say questions of public safety—are to be replied to by the head of the Admiralty, the sooner the Admiralty loses its head the better. Is it not monstrous that a public functionary should be permitted to answer the plain and pressing question,—“Are we taking any step towards arming our navy with rifled guns, as the French are said to be doing?”—by the evasive remark that he, the first lord of the Admiralty, thought it undesirable that he should discuss the “many questions” connected with the “improvement of cannon” in the House of Lords! However ignorant the Duke of Somerset may be of the fact, we can assure him that the question which he thus contemptuously slights is agitating the thoughts of many able and patriotic officers of the navy, and other gentlemen, at this moment. We have had it from the lips of several of them, that, in their judgment, the policy of waiting for, and depending almost exclusively upon, the Armstrong gun is in the highest degree imprudent and dangerous.

We have no predisposition to panic in connection with our national defences, but we submit that the rapid armament of French vessels with rifled cannon, which is said in the best quarters to be now in progress, is a matter of the most momentous nature. And we further submit that if the Duke of Somerset have any genuine patriotism in him, and if he be in any way worthy to control the navy of the people of England at this crisis, he will not be content with saying he is without authentic information on the subject, but will at once bestir himself, and put himself in possession of such information, and act vigorously, if need be, upon it. If our informant and the statements of our greatest contemporary are to be relied upon, the French are rapidly producing large numbers of rifled cannon for the navy; and it will be perilous indeed for us if the first lord of our Admiralty is to be the last man in England to learn the fact.

Since the above was written the *Times* has been provoked by the Duke of Somerset to the publication of an article upon this subject. The editor says:—"The Armstrong gun will, no doubt, be an astonishing weapon; but as yet we have only one or two specimens of it. The works are only in course of erection, all the machinery has to be brought into order, and the utmost that we are promised is a hundred Armstrong guns by the end of the year. Even this promise is hardly likely to be kept. On the other hand, thousands of Armstrong guns will be required for our ships, our fortresses, and for service in the field. The construction of these must be the work of several years. In the meantime what is going on across the Channel? The most noticeable feature in the Arsenal," writes our *Marseilles* correspondent, "is the effort made to provide rifled ordnance for the Navy. The system

"which appears to be definitely adopted consists of three grooves about three inches broad and an eighth of an inch deep, with a twist of one-sixth." These guns are being supplied rapidly to the French line-of-battle ships. It would certainly seem but a prudent step to make use of the guns we have as supplemental to the 'Armstrongs,' which must be comparatively few in number for the next two or three years. There are, we believe, no less than 7,000 smooth-bored guns now lying at Woolwich Arsenal. To rifle a part of these would be an easy and, comparatively, an inexpensive work. If beyond the powers of the Government establishments, the work might be distributed among the various factories in our great towns, and by the end of the year large numbers of rifled guns might be fit for use."

In another article we show that the Americans are adopting means for rifling their bronze ordnance.

It may seem strange to some to say so, but we do not hesitate to believe that the Lancaster gun is, after all, that to which we must look for a successful settlement of this question of rifled guns for the Navy. Those which burst in the Crimean war were merely ordinary service-guns turned out to an oval bore, and their failure in no way proved the principle bad. On the contrary, recent experiments have amply demonstrated the soundness of the principle. We know also that the Lancaster gun can be produced in large numbers with great rapidity. These two facts taken together justify us, we submit, in the confidence we feel in this extraordinary but simple weapon, which will, we are sure, speedily prove itself inferior to none in this or any other country.

THE NEW AMERICAN RIFLED CANNON.

THE Americans are not disposed to fall far behind the more belligerent nations of the Old World in their implements of war. At Chicopee, Massachusetts, experiments have lately been made with a new rifled cannon, the invention of General James, which promises extraordinary results. From a synopsis of the official report of the Board who superintended these trials, which has just reached us, we learn that the guns examined were a 6-pound bronze cannon, with 3·80 inch calibre, and rifled 15 grooves; a 12-pounder, 4-inch calibre and same number of grooves. In both instances, the twist in rifling was equivalent to one turn in 60 feet at the beginning, and ending in one in 20. The projectile designed by General James for these guns is a cast-iron cylinder pointed by a solid conoidal head, the diameter being only 1/2 of an inch less than the bore of the gun, and the length twice the diameter of the calibre. The cylinder retains its full diameter for a quarter of an inch of its length at each end. For the intermediate length its diameter is reduced half-an-inch, forming a recess in its body, which is filled by a compound of canvas, sheet-tin, and lead. The base of the cylinder has a central cavity or opening of 1·95 inches in diameter, and 1·5 inches deep. When the charge is fired the gas evolved by the burning of the powder, in its efforts to expel the projectile and to escape from the gun, is forced into the cavity against the compound filling, which is thereby pressed into the grooves of the bore, and by its firm hold in them the rotary motion is imparted to the projectile.

The Board having examined the guns and projectiles, proceeded to test their efficiency, the results obtained being very satisfactory. The report says, respecting the guns, their merit is due to the rifling, which can be readily applied,

at little cost, to all bronze cannon of the United States, and so render them as far superior to the present smooth bore guns as, in small arms, the most improved rifle surpasses the musket. The depth of grooving is so shallow as in no wise materially to impair the strength of the gun, while it is sufficient to compel the projectile to take the rifle flight. The effect of these contrivances was exhibited in an extraordinary manner, by the increased range obtained while using the same charge of powder and elevation in projecting masses of double the weight of the usual spherical balls. The merits of the projectile are represented to consist in their answering fully the expectations desired of them; their ready fabrication and adaptation to guns; their ease in loading; the certainty of the expansion of the filling and its firm hold in the grooves of the guns. The greased canvas wipes the rifling clean and leaves the bore in condition readily to receive the next charge, and which is also a sure protection to the bore from injury. For these reasons the gun and projectiles are commended to the favourable consideration of the Government; and as the experimental firing was subject to several disadvantages which may hereafter be avoided, the Board recommend that guns of the service calibre be granted to General James for rifling according to his principle.

We learn that another series of experiments is in contemplation, in which will be compared, side by side, the performances of this new gun with those now in use. Of course the remarkable precision and power of the new rifled ordnance constitute its chief value, but the great saving of ammunition effected is a matter of no small importance. The results of the experiments above referred to are expressed in tabular form, at much length. As an example, it is shown that in one instance 18 shots were fired a mean distance of 674 yards, at an elevation of one degree—the powder weighing $1\frac{1}{4}$ lb., the projectile $12\frac{1}{2}$ —the deviation being only four inches to the right of centre, and half an inch above it. On reaching ground the missile was buried five feet in compact sand. In another instance a shot was fired 2,050 yards, at an elevation of five degrees, and passed about 25 feet above the top of the hill towards which it was directed. The Board believe, from the testimony of several witnesses who were near the range, that the projectile "continued its flight many hundred yards beyond the hill," the summit of which was nearly on the same level as that upon which the gun was placed in battery. According to the statement of Mr. Ames, the manufacturer of the gun, who carefully examined the ground, "it is almost certain the ball went four miles." After what is already known it is safe to say that any object within the reach of an ordinary spy-glass is a fair mark for this terrible weapon.

In one other respect the exploits of General James's gun demand attention. "According to the laws of projectiles laid down in the Ordinance Manual, and which have long been established, as was supposed beyond power of refutation, the range of a 6 lb. shot at five deg. elevation and $1\frac{1}{4}$ lb. powder is," says the *New York Journal of Commerce*, to which we are indebted for this information, "1,523 yards; but, in the example now afforded, a ball $12\frac{1}{2}$ lb., with the specified quantity of powder, has gone between three and four miles. As compared with the celebrated Armstrong gun, the results are not less curious. Mr. A. claims to have thrown a ball $5\frac{1}{2}$ miles with six pounds of powder, employing an area or calibre of $3\frac{1}{4}$ inches—which is a result of 55-100ths less favourable than that obtained by the experiments at Chicopee. According to the latter,

"any gun of a calibre equal to Armstrong's will throw a ball, with less than half the powder, the full distance attained in his practice."

PRE-ADAMITE MECHANICS AND THEIR TOOLS.

A VERY curious controversy has lately sprung up among our geologists and antiquaries respecting the duration of man's past existence upon the earth, the occasion of it being the discovery in several places of various flint-implements which appear to have been the tools of some very ancient race of mechanics. These tools consist, first, of certain flint-flakes, shaped apparently for arrow heads or knives; secondly, of certain pointed flint weapons truncated at one end, and intended probably for lance or spear-heads; and, thirdly, of certain oval or almond-shaped flint implements with a cutting edge all round, which were used, it is thought, as sling stones or as axes. It has been found that in form and workmanship—for all seem to agree that they are products of workmanship—the two last classes differ essentially from the implements of what is called the Celtic period, which are usually more or less ground and polished, and cut at the wide and not the narrow end. All these flint implements have been discovered, very remarkably, in intimate association with the remains of extinct races of animals, and in undisturbed beds of drift of a geological period hitherto considered long antecedent to the existence of man upon the earth.

Mr. Joseph Prestwich, a Fellow of both the Royal and the Geological Societies, has lately furnished a paper to the Royal Society in which he very temperately states the facts hitherto ascertained in reference to these strange discoveries. He commences by noticing how comparatively rare are the cases even of the alleged discovery of the remains of man or of his works in the various superficial drifts, notwithstanding the extent to which these deposits are worked; and of these few cases so many have been disproved, that man's non-existence on the earth until after the latest geological changes, and the extinction of the Mammoth, Tichorhine Rhinoceros, and other great mammals, had come to be considered almost in the light of an established fact. Instances, however, have from time to time occurred to throw some doubt on this view, as the well-known cases of the human bones found by Dr. Schmerling in a cavern near Liège—the remains of man, instanced by M. Marcel de Serres and others in several caverns in France—the flint-implements in Kent's Cave—and many more. Some uncertainty, however, has always attached to cave-evidence, from the circumstance that man has often inhabited such places at a comparatively late period, and may have disturbed the original cave-deposit; or, after the period of his residence, the stalagmitic floor may have been broken up by natural causes, and the remains above and below it may have thus become mixed together, and afterwards sealed up by a second floor of stalagmite. Such instances of an imbedded broken stalagmitic floor are in fact known to occur; at the same time the author does not pretend to say that this will explain all cases of intermixture in caves, but that it lessens the value of the evidence from such sources.

The subject has, however, been latterly revived, and the evidence more carefully sifted by Dr. Falconer; and his preliminary reports on the Brixham Cave,* presented last year to the Royal Society, announcing the carefully

* On the 4th of May, this year, Dr. Falconer further communicated to the Geological Society some similar facts, though singularly varied, recently discovered by him in the Mascagnone Cave near Palermo.—See Proc. Geol. Soc.

determined occurrence of worked flints mixed indiscriminately with the bones of the extinct cave bear and rhinoceros, attracted great and general attention amongst geologists.

In 1849 M. Boucher de Perthes, President of the "Société d'Emulation" of Abbeville, published the first volume of a work entitled "Antiquités Celtiques et Antédiluviennes," in which he announced the important discovery of worked flints in beds of undisturbed sand and gravel containing the remains of extinct mammalia. Although treated from an antiquarian point of view, still the statement of the geological facts by this gentleman, with good sections by M. Ravin, is perfectly clear and consistent. Nevertheless, both in France and in England his conclusions were generally considered erroneous; nor has he since obtained such verification of the phenomena as to cause so unexpected a fact to be accepted by men of science. There have, however, been some few exceptions to the general incredulity. The late Dr. Rigollot, of Amiens, urged by M. Boucher de Perthes, not only satisfied himself of the truth of the fact, but corroborated it in 1855 by his "Mémoire sur des Instruments en Silex trouvés à St. Acheul." Some few geologists suggested further inquiry; whilst Dr. Falconer, himself convinced by M. de Perthes' explanations and specimens, warmly engaged Mr. Prestwich to examine the sections.

Mr. Prestwich, who confesses that he undertook the inquiry full of doubt, went last Easter, first to Amiens. On his first visit he obtained several specimens from the workmen, but he was not successful in finding any himself. On his arrival, however, at Abbeville, he received a message from M. Pinsard of Amiens, to inform him that one had been discovered the following day, and was left *in situ* for his inspection. On returning to the spot, this time with his friend Mr. Evans, he satisfied himself that it was truly *in situ*, 17 feet from the surface, in undisturbed ground, and he had a photographic sketch of the section taken.* Dr. Rigollot also mentions the occurrence in the gravel of round pieces of hard chalk, pierced through with a hole, which he considers were used as beads. Mr. Prestwich found several, and recognised in them a small fossil sponge (the *Coccinopora globularis*, D'Orb), from the chalk, but does not feel quite satisfied about their artificial dressing. Some specimens do certainly appear as though the hole had been enlarged and completed. The only mammalian remains Mr. Prestwich here obtained were some specimens of the teeth of a horse, but whether recent or extinct, the specimens were too imperfect to determine; and part of the tooth of an elephant (*Elephas primigenius*?). In the gravel-pit of St. Roch, $1\frac{1}{4}$ mile distant, and on a lower level, mammalian remains are far more abundant, but the workmen said that no worked flints were found there, although they are mentioned by Dr. Rigollot.

At Abbeville, Mr. Prestwich was much struck with the extent and beauty of M. Boucher de Perthes' collection. There were many forms of flints in which he, however, failed to see traces of design or work, and which he only considered as accidental; but, with regard to those flint-instruments termed "axes" ("haches") by M. de Perthes, he entertains not the slightest doubt of their artificial make. They are of two forms, generally from four to ten inches long. They are very rudely made, without any ground surface, and were

* On revisiting the pit, since the reading of his paper, in company with several geological friends, Mr. Prestwich was fortunate to witness the discovery and extraction by one of them, Mr. J. W. Flower, of a very perfect and fine specimen of flint-implement, in a seam of ochreous gravel, 20 feet beneath the surface. They besides obtained thirty-six specimens from the workmen.—June, 1859.

the work of a people probably unacquainted with the use of metals. These implements are much rarer at Abbeville than at Amiens. Mr. Prestwich was not fortunate enough to find any specimens himself; but from the experience of M. de Perthes, and the evidence of the workmen, as well as from the condition of the specimens themselves, he is fully satisfied of the correctness of that gentleman's opinion, that they there also occur in beds of undisturbed sand and gravel. Besides the concurrent testimony of all the workmen at the different pits, which Mr. Prestwich after careful examination saw no reason to doubt, the flint-implements ("haches") bear upon themselves internal evidence of this opinion. It is a peculiarity of fractured chalk flints to become deeply and permanently stained and coloured, or to be left unchanged, according to the nature of the matrix in which they are imbedded. In most clay beds they become outside of a bright opaque white or porcelainic; in white calcareous or siliceous sand their fractured black surfaces remain almost unchanged; whilst in beds of ochreous and ferruginous sands, the flints are stained of the light yellow and deep brown colours so well exhibited in the common ochreous gravel of the neighbourhood of London. This change is the work of very long time, and of moisture before the opening out of the beds. Now in looking over the large series of flint-implements in M. de Perthes' collection, it cannot fail to strike the most casual observer that those from Menchecourt are almost always white and bright, whilst those from Moulin Quignon have a dull yellow and brown surface; and it may be noticed that whenever (as is often the case) any of the matrix adheres to the flint, it is invariably of the same nature, texture, and colour as that of the respective beds themselves. In the same way at St. Acheul, where there are beds of white and others of ochreous gravel, the flint-implements exhibit corresponding variations in colour and adhering matrix; added to which, as the white gravel contains chalk debris, there are portions of the gravel in which the flints are more or less coated with a film of deposited carbonate of lime; and so it is with the flint-implements which occur in those portions of the gravel. Further, the surface of many specimens is covered with fine dendritic markings. Some few implements also show, like the fractured flints, traces of wear, their sharp edges being blunted. In fact, the flint-implements form just as much a constituent part of the gravel itself—exhibiting the action of the same later influences and in the same force and degree—as the rough mass of flint fragments with which they are associated.

With regard to the geological age of these beds, Mr. Prestwich refers them to those usually designated as post-pliocene, and notices their agreement with many beds of that age in England. The Menchecourt deposit much resembles that of Fisherton near Salisbury; the gravel of St. Acheul is like some on the Sussex coast; and that of Moulin Quignon resembles the gravel at East Croydon, Wandsworth Common, and many places near London. The author even sees reason, from the general physical phenomena, to question whether the beds of St. Acheul and Moulin Quignon may not possibly be of an age one stage older than those of Menchecourt and St. Roch; but before that point can be determined, a more extended knowledge of all the organic remains of the several deposits is indispensable.

Mr. Prestwich next inquires into the causes which led to the rejection of this and the cases before mentioned, and shows that in the case of M. de Perthes' discovery, it was in a great degree the small size and indifferent execution

of the figures, and the introduction of many forms about which there might reasonably be a difference of opinion; in the case of the arrow-heads in Kent's Cave a hidden error was merely suspected; and in the case of the Liège Cavern he considers that the question was discussed on a false issue. He therefore is of opinion that these and many similar cases require reconsideration; and that not only may some of these prove true, but that many others, kept back by doubt or supposed error, will be forthcoming.

One very remarkable instance has been already brought out. In the 13th volume of the "Archæologia," published in 1800, is a paper by Mr. John Frere, F.R.S. and F.S.A., entitled, "An Account of Flint-Weapons discovered at Hoxne, in Suffolk," wherein that gentleman gives a section of a brick-pit in which numerous flint-implements had been found, at a depth of eleven feet, in a bed of gravel containing bones of some unknown animal; and concludes, from the ground being undisturbed and above the valley, that the specimens must be of very great antiquity, and anterior to the last changes of the surface of the country—a very remarkable announcement, hitherto overlooked.

Mr. Prestwich purposely abstains for the present from all theoretical considerations, confining himself to the corroboration of the facts:—"1. That the flint-implements are the work of man. 2. That they were found in undisturbed ground. 3. That they are associated with the remains of extinct mammalia. 4. That the period was a late geological one, and anterior to the surface assuming its present outline, so far as some of its minor features are concerned."

He does not, however, consider that these facts, as they at present stand, of necessity carry back man in past time more than they bring forward the great extinct mammals towards our own time, the evidence having reference only to relative and not to absolute time; and he is of opinion that many of the later geological changes may have been sudden or of shorter duration than generally considered. In fact, from the evidence here exhibited, and from all that he knows regarding drift phenomena generally, he sees no reason against the conclusion that this period of man and the extinct mammals—supposing their contemporaneity to be proved—was brought to a sudden end by a temporary inundation of the land; on the contrary, he sees much to support such a view on purely geological considerations.

All are not, however, so temperate as Mr. Prestwich. Many have already taken sides upon the question; the one side contending that man—and man as a mechanic, too—is a much more venerable being than the other side will admit. We shall probably recur to the subject on an early occasion.

THE WORKING MAN: HISTORY OF HIS PROGRESS.

THE orthodox division of society amongst us English people is into three classes. The carriages of a railway-train are of three classes. The seats of a theatre are of three classes. In public print and talk three classes are acknowledged: middle, upper, and lower. This is quite right; there are three and only three; though which is highest and which lowest we cannot say, but should call him happiest who belongs to all of them. The three classes of society, then, are these: thinkers—workers—and another class, difficult to name, who are distinguished by character and beauty of demeanour and life, rather than by thought or action. Only as belonging to one or all of these classes are men to be revered

or honoured. The history of the modern workman or handicraftsman—his ascent from serfhood to manhood—is the grandest fact in European history. The few great events that evolved this fact of facts were as the tollings of the hours on the world-dial, whose hours are centuries. We chronicle them here to set the reader's mind thinking of them afresh. But first, one word about the material to be wrought upon—the Teutonic race.

The strongest element in shaping a people's destiny is peculiarity of race. We have a signal example of this in the Gallic blood of our neighbours across the Channel. How excitable they are—mobile, quickly susceptible of change for better or worse. How sociable, communicative, wearing their secret on their tongue. How demonstrative to vainness, personal and national! What a generous, high-mettled people! Thus, 'tis said that Louis Philippe's Government fell in 1848, because it appealed to nothing generous and high in the people; based itself only on material interests; set up the cash-box and ledger for worship; warning against revolutions as bad for trade.

In tracing the history of Anglo-Saxon freedom we find the germ of it in the race. Tacitus, the first keen, cultivated observer of the German tribes, said of them that they were remarkable for personal attachment, trust in one another, devotion and loyalty to one another. This gravitation of man to man is the fountain of liberty. Infinite space makes not liberty; liberty is an orbit of one's own, springing from mutual attractions and reciprocities.

The earliest civiliser of our wild ancestors was the sight of the external civilisation of the peoples they conquered: Roman roads, aqueducts, towns, municipal institutions, civil laws.

Feudalism was the first social form into which modern Europe crystallised. Guizot thus pictures the owner of the fief or feud:—

"Let us examine feudal society as it is in its own nature, looking at it first of all in its simple and fundamental element. Let us figure to ourselves a single possessor of a fief in his own domain; and consider what will be the character of the little association which groups itself around him. He establishes himself in a retired and defensible place, which he takes care to render safe and strong; he there erects what he terms his castle. With whom does he establish himself there? With his wife and his children: probably, also, some few freemen who have not become landed proprietors have attached themselves to his person, and remain domesticated with him. These are all the inmates of the castle itself. Around it, and under its protection, collects a small population of labourers—of serfs, who cultivate the domain of the seigneur. Amidst this inferior population religion comes, builds a church and establishes a priest. In the early times of feudality, this priest is at once the chaplain of the castle and the parish clergyman of the village; at a later period the two characters are separated. This, then, is the organic molecule, the unit, if we may so speak, of feudal society."

In these feudal times, reaching from the 10th century to the 15th—the middle ages, as we call them—the workman was a serf, the property of his lord, a part of his goods and chattels. Much as the Teutonic personal devotion and loyalty modified this condition, the labourer was essentially a slave.

It is impossible to over-rate the power of the old Catholic church in those centuries. Fancy yourself in one of our old churches seven centuries ago, when high birth was the sovereign possession in Europe. The baron—rugged, valiant, proud—and the dull dim serf, in the chime of Sunday bells, have crossed heath and meadow in the summer sunshine: there under Gothic arches, in the light of the coloured window, rich as a July sunset behind English elms, in the hearing of these is read the old words, "Put on the new manhood, wherein is neither barbarian, Scythian, bond, nor free;

"but intelligence and worth are all in all." That reader, in his person and in his book, represents self-discipline and gentleness amidst war and brigandism—genius, intelligence, and learning amidst pride of descent and brute force. No one in that building is higher than he, and he is perhaps the son of a herdman. The monastery he belongs to is the only haunt of learning in that whole region. There is better tillage of the earth there than on the baron's estate; a knowledge and skill of handicraft and manufacture wholly unknown elsewhere. There, too, is spoken and practised the grand sentiment for the industrial ages: *Bene laborare est bene orare*; To work well is to pray well.

This is no idle sentimentality about those old ages. It is a fact, growing clearer and clearer, that the old Catholic church was the first great civiliser and humaniser of modern Europe. In the middle ages she was the foremost fact. She literally saved and preserved the learning of antiquity; she fostered the ruder and finer arts; she educated the serf to be a priest, or cardinal, or even pope; she stood between the serf and his lord; in one of her earliest quarrels with the nobility, her clergy were reproached as "the sons of serfs." And it has been well pleaded, that had she not been the huge European organism she was, she could not have checked the violence of kings and nobles.

It should be observed that in England the power of the feudal baron was a far more limited one than on the Continent. Norman William made his barons immediately responsible to him; allotted the land of each in places distant from each other; while, again, the people they had conquered were almost as strong as themselves: hence the closer union between the nobles and the people. The Magna Charta, wrung by the barons from John, was as much a people's as a nobles' charter.

Again, the first crusade was a great awakening of the people. Kings, chiefs, vassals, and serfs, were for the first time inspired with a grand aim in common. "That remarkable expedition was the first great event of modern times which had a European and a Christian interest—an interest not of nation, or place, or rank but which the lowest serfs had in common, and more than in common, with the loftiest barons. When the soil is moved, all sorts of seeds fructify. The serfs now began to think themselves human beings."*

How finely M. de Tocqueville depicts this movement of liberty. "The erection of corporate towns introduced an element of democratic liberty into the bosom of feudal monarchy; the invention of fire-arms equalized the villen and the noble on the field of battle; printing opened the same resources to the minds of all classes; the post was established, so as to bring the same information to the door of the poor man's cottage and to the gate of the palace; the discovery of America offered a thousand new paths to fortune, and placed riches and power within the reach of the adventurous and the obscure."

Of all material things trade was the strongest in emancipating the people. Every new invention, luxury, and want made the workman of more value to society, while it kindled his ingenuities and raised him higher as a man. Mentally, the Reformation was the greatest quickener of the people of Europe to individuality and self-esteem. Every man found himself called on to think, to form a judgment, to take sides, and often to stake goods and life for his cause.

* J. S. Mill's Review of Michelet's History of France.

But what is the true elevation of the working classes? Stephenson, the founder of the railway, was a poor lad, earning twopence a-day at watching cows, because his father was too poor to send him to school; and at public meetings of mechanics and artisans he used to hold up this success of his as a stimulus to the workmen:—"Persevere as I have done, and you will get on." Now, any youth growing independent of others, standing on his own feet, cutting out his own path, is always a fine spectacle. We confess to a thrill of delight at the sight of a poor lad, by unaided effort, rising to any real eminence, were it merely of wealth. But it is a poor, vulgar aim to hold up to working men, that of rising above their own class merely—at any price to better their livelihood. Yet this is the tone of some of our eminent teachers. We remember an address of Sir Bulwer Lytton's to the boys of one of our public schools, in this strain:—"I set out in life determined to be something; aspire, and you will rise." Lord Palmerston the other day addressed university students in the same spirit:—"Every department of labour is crowded; you must struggle and fight to win." All this may be very well; but the high-minded man asks, Persevere—aspire—fight—for what?

Now we would suggest that the end of life is not to grow rich, or learned, or famous—but to live. To live, first, bodily; not to be cooped up in a place and employment where your senses and limbs have no free play: above all to keep intellect, imagination, taste, affection alive; to put forth all your powers; to taste the whole round of existence; to be able to say at the end of every day, every year, aye, at the end of life itself—"I have lived." That we have remained in the same social class we were born in, have followed the same humble calling as our fathers, is a small matter; but that our intelligence has grown larger and larger; our manners and thoughts more and more beautiful and magnanimous; that our whole life is truthful, and brotherly, and lofty, rich in relationship and fellowship, enjoyment and influence—this is success—the true rising of the working man!

THE WRECK CHART.

We have lying before us a remarkable map—the Wreck Chart of the British Isles for 1858. It is to be found in a return to Parliament, carefully prepared by the Board of Trade. The chart is of the same appearance as an ordinary map of these islands, except that the whole line of coast, from the Orkneys to the Land's End, is dotted with a series of black marks. Each mark indicates either a shipwreck or some casualty to a vessel nearly approaching that disaster. A most melancholy effect has this chart when this key to its object is given. The whole coast, particularly near the approaches to our great commercial cities, bristles with the dottings which indicate clearly the site where some noble ship has gone to destruction with her human freight. All round our coast, with the aid of this valuable map, we can trace clearly the frightful work of destruction during the past year. The total number of British merchant ships, including steamers, is supposed to be 27,097, giving a tonnage of 4,558,730. These ships are handled probably by no less than 300,000 men and boys.

The nature of the disasters to British and foreign ships is thus epitomized:—In 1858 the number of vessels wrecked on the coast and in the seas of the United Kingdom was 1,170; of these 354 were total wrecks, 50 sunk by collision, making the number totally lost 404. Vessels stranded and damaged so as to require

to discharge cargo 515, by collision 251, total 766; making the whole number of wrecks 1170. By these disasters the lives of 1,865 persons were imperilled, of which number 340 persons or 18 of the whole were actually lost.

This is the dark side of the doleful map. It has, however, a bright side, and on that we find that by the life-boats of the National Life-boat Institution, those of local bodies, and various other craft, 1,555 of our fellow-creatures were, during the past year, rescued from a watery grave. The red dottings on this unique chart are cheering marks, as indicative of the places where life-boats and the life-preserving apparatus are to be found in the hour of distress. The latter are under the control of the Board of Trade, and as the firing of the apparatus requires some knowledge of gunnery, they are principally in the charge of the coast guard.

It is very gratifying to find that life-boats on dangerous points of the coast have, of late years, greatly increased in number and efficiency under the management of the National Life-boat Institution, whose energies in this good work are untiring. It has now eighty-two life-boat establishments under its management, and we only wish that we were able to report that it had twice that number, for there are still too many exposed points in need of these arks of mercy; and although shipwrecks will occur, notwithstanding all our precautions, yet if life-boats were more numerous on the coast, and if ship-owners paid more attention to the condition of their vessels and crews before they sent them to sea, much might unquestionably be done to lessen the melancholy disasters on the coast of the British Isles.

SMALL-ARMS FACTORY AT ENFIELD.

THERE are not many manufactories in the kingdom which are of more immediate importance to the public at this moment than those wherein heavy guns and small arms are manufactured and never, fortunately, was the rate of production greater in either case than now. At Woolwich gun foundries, with all the rapidity contingent upon increased facilities and more room, they are turning out the former; whilst at Enfield the smaller—but not less necessary implements of war—rifles, are completed with a speed almost incredible. Of Woolwich we have aforetime rendered an account to our patrons, the public, and it is now intended to give some information as to Enfield.

A few years back and it might have been advisable to have given, by way of preface, the geographical position, and means of getting to this place; but now all know its whereabouts, and such a course is quite unnecessary. The exterior of the small-arms factory at Enfield Lock is constructed after an elegant design, and cannot fail to create an agreeable effect on the mind of the visitor, be that mind scientifically trained or not. It is of considerable size, but unfortunately the interior of the edifice is not equal in beauty to the exterior—unfortunately, we say; but since the useful predominates inside, it may be admitted that that fact is a set-off against the merely ornamental character of the outside. The arrangement of machinery within the walls is simple. There, in one large square room, in which perhaps 700 hands, young and old, are engaged, are placed the machines for fabricating the furniture, stocking, locks, screw-sights, bayonets, &c., &c. for rifles. Some of these machines are of exceedingly ingenious construction, and they are all kept in excellent condition. The plant of machinery for the production of the stocks is of American origin, and the Messrs. Ames and Co., of Massachusetts, figure largely in the inventive way. Messrs. Greenwood and Botley, of our own town of Leeds, have, however, effected considerable improvements in point of detail, whilst, as stated recently, Messrs. Hayes, Hague, and Williams,

foremen of the various departments at Enfield, have won not only "golden opinions," but more substantial rewards for valuable alterations and modifications suggested and made by themselves. To mention one of these as carried out to practical use by Mr. Hayes, we may adduce that pertaining to the "swivel," which is a link to connect the "main-spring" with the "tumbler" of the rifle. Swivels are made complete, thanks to this gentleman's skill, by machines, from bars of $\frac{1}{4}$ in. steel; and all are so perfectly manufactured that they inevitably fit a test-receiving gauge. Of the "tumbler" and "bridle" machinery it would be difficult, without drawings, to give clear explanations. It comprises a simplification of the principle of the Rose engine, and does not require in working the attention of skilled workmen. Since the appliances produced by the tumbler and bridle machines are of a very minute and delicate description, it may be imagined that much patient ingenuity was exercised in perfecting them, and this is true. At the rate that the Enfield rifle, of the pattern 1853, is being made, these little improvements, moreover, are great enough in their consequences to save fully £2,000 per annum to the country.

From the large room, in which multifarious operations are going on with unflagging regularity, one passes forward to the Smithy; and here again machinery has been brought to bear with wondrous precision. Everything prepared in this department is touched more or less by machine power. From this commodious and convenient apartment doors open into all the following:—the tool-department, where all tools are made and repaired; the hardening-room, where all the bayonets, main-springs, sear-springs, and ramrods are tempered; the polishing-room; grindery; and various places of comparatively minor importance. A pair of 40-horse power engines, fitted with Fairbairn's expansive valve motion, drive the whole of the machines, whose "name is legion," in the above-named branch of the Rifle Factory. On the opposite side of a basin or mill-head stands another building, parallel with that mentioned above. This is of extensive dimensions, and two stories high; and here the barrels are manufactured. Combined steam and water power is used in giving motion to the machinery in the barrel department; and this consists of a 25-horse power condensing engine, with one 20 and one 25-horse breakwater wheel.

With regard to the prime cost of a finished Enfield rifle of the approved 1853 pattern, it may be said that it is about £2 5s. It is a most serviceable weapon; and, from the extreme accuracy with which its parts have been fitted, and the power of interchanging them, it has an advantage over all hand-made guns. A defective part can be replaced at once without fitting. When all the component parts have been carefully tested by viewers, or inspectors, especially kept for the purpose, and who have a thorough knowledge of their duties, it is next to impossible that there should be differences. In fact, so wondrously true are all the machine-prepared parts of the rifle to each other, that a workman will take up the requisite pieces indiscriminately from boxes full of them, and put a rifle together before your eyes in three minutes! From fifteen to eighteen hundred rifles per day of ten hours are at present being finished at Enfield Factory, and this gives (nearly) an average of one rifle completed from the material every two minutes, and made fit for shooting down an invader!

Altogether the number of persons employed amounts to somewhere near 1,500, and the offices and stores are admirably arranged. Colonel Dixon, of the Royal Artillery, a most persevering and exemplary gentleman, assisted by J. H. Burton, Esq., an American, and Chief Engineer, have the control of the entire establishment, which is conducted, so far as we can judge, in a most efficient manner.

Looking at the state of affairs across the Channel, Government and people here may well look also towards Enfield.

MAJOR RHODES' PATENT TENTS.

IN our last volume we published an elaborate description of Major Rhodes' improved tents for army and other purposes, and expressed our high sense of their value. These tents having recently been brought under the notice of the authorities at the Horse Guards, the Duke of Cambridge gave directions for two of the tents to be pitched at Chatham garrison, in order to put to a practical test the superiority of the invention over the ordinary military tents now in use by the army when encamped at Aldershot, the Curragh, Chatham, and other military stations. Two of the tents have accordingly just been erected on the grounds adjoining the Garrison Hospital at Chatham, under the personal superintendence of Major Rhodes. "During the storm and hurricane which swept over Chatham on Wednesday night," says the *Times* Chatham correspondent, "they were found to be in every respect superior to the ordinary tents erected near the same spot. . . . After the tent had been fixed on Wednesday afternoon, ten of the portable bedsteads from the hospital were moved into it, and as many patients directed to take possession of them. Notwithstanding the tremendous storm which raged early yesterday morning, not the slightest inconvenience was experienced by the inmates, who slept as dry as in an ordinary room, while many of the other tents admitted the water, which poured in as through a sieve. Major Rhodes' hospital tent can be pitched by eight men in 12 minutes; and, whereas in the present tents there are about 150 pegs and 70 ropes to each, the new invention has only about 40 pegs and 12 ropes to secure it, there being no necessity for the men to turn out in the rain during the night to 'slack' the ropes as with the present tents—a serious matter when that duty has to be performed by sick patients."

The advantages of Major Rhodes' tents over those of the Government may be briefly noticed. His hospital tent weighs about 112 lbs. less than the Government hospital-marquee, and its cost is about £3 under the Government contract price. The ventilation is most efficient, and subject to the control of the medical officer—impervious to wet, and the strong rays of the sun—can be pitched in 12 minutes by 8 men. The Hanoverian Government (who have practically tested this tent) pronounce that Rhodes' hospital tent affords the best shelter hitherto obtained in camp hospitals, &c. The price of a Government hospital marquee, 30 feet wide by 14½ feet, and 14 feet in height, is from £33 to £35, and weighs (in three packages) from 507 lbs. to 652 lbs. (the latter weight includes 4 ground sheets.) It affords accommodation for from 18 to 20 patients. Major Rhodes', 20-foot diameter, field-tent cost £24, viz. about £12 cheaper, and weighs (in 2 packages) 230 lbs., viz. 277 lbs. less than the Government hospital marquee. It offers accommodation for from 18 to 20 patients. Two of Major Rhodes', 20-foot diameter, field tents can be pitched by 4 men (in about 8 minutes for each tent), on about the same space of ground as is requisite for only one Government hospital-marquee; and further, from 10 to 14 men require from 15 to 20 minutes to pitch the latter tent. Major Rhodes' tent provides detached accommodation for 24 rifles, 24 sets of accoutrements, and 24 knapsacks, with a perfect system of ventilation; in which very important points the Government hospital marquee is deficient. Irrespective of cost, &c., it results that by adopting Major Rhodes' tents into the service, healthy shelter can be provided for about 45 men, allowing the same amount of transport as is at present necessary for conveying only one Government hospital marquee, which latter only affords accommodation for 20 men; thus showing a clear saving of more than one hundred per cent. in cost of transport, which, with an army in the field, would be a very great relief to the Commissariat Department.

We now learn that the officers appointed to examine Major Rhodes' tents at Chatham are about to report most strongly in their favour to the Commander-in-Chief.

BREAKWATER AT THE PORT OF BLYTH.

BY MICHAEL SCOTT, C.E.

THE following article is abridged, and the accompanying engravings are reduced, from the official proceedings of the Institution of Civil Engineers:—

The Port of Blyth is situated on the coast of Northumberland, about ten miles north of the river Tyne. It need hardly be stated that the whole surrounding district is rich in coal, there being a large virgin field of steam-coal in the immediate vicinity of Blyth. Until recently only a small class of vessels could trade to that port, and a great part of the coal raised in the neighbourhood was transmitted by rail to the Tyne for shipment. But a few years ago a company of enterprising gentlemen, headed by the lord of the manor, Sir M. W. Ridley, associated themselves, and obtained powers for improving the harbour. Mr. James Abernethy, M. Inst. C.E., was engaged as engineer-in-chief, and under his direction the works were commenced. Certain reasons, with which the author need not trouble the Institution, induced him to undertake the construction of a portion of these works; and merely observing, that the present communication has reference exclusively to the breakwater, he will proceed to describe it in detail.

It is well known that there is a very heavy sea on this part of the coast; and that this must be the case will be obvious, when the great reach of water east and north is taken into consideration, the nearest land being the coasts of Norway and Denmark, which are distant from 400 miles to 500 miles. But it is not so commonly understood that gales spring up with a suddenness which increases the peril to men, and the risk of injury to works in progress. It is necessary to note this peculiarity, because it increased the difficulty of carrying out the work as originally designed. For a length of a mile the river was exposed to the action of the sea, and it followed that no vessel could then lie in this portion of, what is now, the harbour. Along the seaward side of the river there is a rocky reef, and upon the base thus provided by nature the breakwater has been erected. The work was originally intended to be, and for a length of 1,800 feet was constructed, entirely of stone; but a failure in the supply of material led to a change, which has resulted in the work shown by Figs. 1 and 2. Mr. Abernethy proposed to employ timber and stone, after the manner adopted at Boulogne and Calais, and furnished a design similar in outline to Fig. 1. As the contractor for the work, being aware of the impossibility of obtaining, on the site, stone suitable for facing, and seeing that during very high tides there was great risk of damage to the open end, which had already been injured several times, the author gladly undertook to do all in his power to carry out Mr. Abernethy's views; and after a good deal of consideration, the forms shown in Figs. 1 and 2 were arranged, and were erected with entire success some time ago. It will be observed that those portions of the breakwater which are illustrated by Figs. 1 and 2, consist of a framework of timber, filled with stone, and arranged as follows:—First, there is a sole piece resting on the ground. Upon this sole are raised two uprights, the one next the sea being supported by a strut from the sole piece. Cross-bearers, or half-balks, embracing the uprights, carry the roadway above; and this is protected by a simple handrail. The frames thus formed are placed at intervals of 10 feet from centre to centre, and are tied together, longitudinally, by walings, two on the sea face, and one on the river face, and also by the open planking, the space contained within which is filled with rubble-stone. It will be seen that, in the first section, Fig. 1, this space is triangular, the planking on the river face being on the strut. The object of this arrangement was, partly to provide a sloping surface, and to leave the river-uprights isolated, opposite the entrance of the proposed docks, for the purpose of destroying, as much as possible, the swell which

passes up the river. In the second section, Fig. 2, the exposure, and consequent strength required, being greater, the planking was put upon the river upright, and the whole space was filled with rubble, and was covered with an open flooring of horizontal timbers. The work has added more than 4,000 feet, in length of the river, to the harbour, where there is still-water; and not only effectually breaks the waves, but it acts as a training wall, to direct the current, and to confine, and to intensify within the new limits, the action of the tidal scour. During its erection there was no risk of injury, and no part of the timber-work has been breached, although the weakest portion has been exposed, for more than two years, to as heavy seas as were ever seen on that coast. The cost of the work has been, on an average, about £10 per lineal foot. The timber has all been creosoted, and bids fair to resist decay for many years.

In the case of the portions of the pier just referred to, the site was either dry, or nearly so, at low-water spring tides; but the line upon which it was to be continued led into a depth of 5 feet, or 6 feet at the lowest ebbs, and about 22 feet at high-water spring tides. From this arose the necessity for a change of plan; but in arranging the breakwater, so far as hitherto described, the author's attention had naturally been turned to the question generally; and Mr. Abernethy having suggested that he should attempt the application of timber to deep-water sections, the author considered the subject, and, as early as January, 1857, succeeded in attaining that object, having then designed deep-water sections very similar to those to be described.

This section of the paper will be occupied with a description of the author's improvements in the construction of breakwaters, examples of which are represented in Figs. 3 to 9.

The author divides these works into two classes; those intended for deep water being wave reflectors, and those for shallow water wave breakers. Excepting the wave screen, the reflectors and breakwaters are of a similar character, and consist of a timber casing filled with stone. The stone hearting constitutes the power to resist removal as a whole, and the timber facing secures the stone from being disintegrated, or carried away in detail; so that if the work is moved it must be bodily. Further, the work is so connected together, that each part supports its neighbouring portions: the importance of this will be obvious when it is considered that waves seldom strike any great extent of surface at the same moment. A marked peculiarity of the arrangement is, that there is no tie between the work and the ground. It simply rests on the surface, and the stability depends wholly upon its weight. The author is opposed to the idea of piling the face, and filling in behind with stone, not only because it is difficult and expensive to pile in a sea-way, but because, in his estimation, it is false in principle. For the piles would necessarily bend before they took any appreciable part of the strain, and before they could deflect, the stone backing must have been moved. Piles may, however, be used in some cases, as a convenient method of filling the space between the frames, for the purpose of keeping the stone from spreading; but then, on the author's plan, these piles would be driven subsequently to the erection of the frames, which constitute an efficient staging from which to drive them.

Other leading features are—the framework is so arranged, first, that the strains are, as much as possible, taken in the direction of the length of the timbers, thus developing its greatest strength; secondly, the joints are covered by whole timbers; thirdly, each piece is proportioned to the work it has to do; and lastly, there is such a variety of size, as to admit of average cargoes being wholly worked up without waste. The faces are so tied inwards as to prevent the rubble from being forced out; and whilst the interstices are sufficient for the free escape of air, there is, after a short time, no motion amongst the stones, and conse-

quently no waste. It will be seen that an excellent foundation is secured as the work proceeds; and the lower tie will accommodate itself so perfectly to an uneven surface, that the erection may proceed on sand and on clay, as well as on rock; on broken, as well as on even ground, almost indifferently. A proof that the foundation is sufficient has been afforded by the work at Blyth, where, although the bottom varies from hard rock to soft clay, there is no observable settlement in a length of more than 2,000 feet. The difficulty of obtaining timber of the requisite length, combined with the certainty that single balks would be fractured, on uneven ground, by the superincumbent stone, led to the designing of the chain tie, which has just been referred to.

The round ends, at the entrances to harbours, are proposed to be constructed of planking, arranged like basket-work, by which great strength is obtained.* Moreover, there is considerable elasticity, so that in the event of a ship touching, neither the pier nor the vessel is damaged. When these ends are of comparatively small diameter, as the one now constructing at Blyth, they are tied into the centre; but when large, the frames vary in breadth according to the exposure; that is to say, the face wall, as it may be termed, increases in thickness from the inner or harbour face seaward.

FACILITY OF CONSTRUCTION.

Before entering upon details under this head, the author claims for his improved arrangements one important advantage, viz., that the work is not liable to be breached during erection. Those only who have had to contend with the sea can appreciate this risk; for although every precaution may be taken, still, in the case of vertical walls, of the ordinary kind at least, there is great danger during erection. The stone wall at Blyth, for example, was repeatedly damaged, but no part of the new construction has ever been breached, although exposed to a heavier sea; but, even in instances in which the permanent work has not been much injured, the staging has suffered; whilst at Blyth, the work itself serving for a staging, no loss has arisen from this cause. It is not only loss of money which is avoided, but loss of time; for there is much less risk of the work being interrupted by bad weather.

In the arrangement proposed, no stone of a high class is required, and no dressing. With respect to the timber, it is easily procurable at any port, and it is all converted on shore, the frames being put together complete, and then floated to their place. It might be thought that, in very deep water, the frames would be difficult to manage; but the experience of the author leads him to a contrary opinion, and he would not hesitate to undertake the erection, even in comparatively great depths. With reference to this point it should be remembered that the addition of 9 lbs. or 10 lbs. of creosote per cubic foot materially reduces the floating power of the timber, so that the following is a statement of the buoyancy of a 10-fathom section (Fig. 6). Supposing the whole timber immersed, the total buoyancy would only be 15 cwt. per foot run of the breakwater; but as the timber is not wholly immersed, there is no buoyancy. At half-tide, when standing on end, each frame would have a weight, or downward pressure, equal to 8 cwt. to sink it. The timber-work, when finished, will have a downward pressure of 25 cwt. per foot run. Thus, it appears, that the weight to be lifted is but little, and that the frame, in position, can easily be made to gravitate sufficiently to steady itself until secured.

In the direction of the length of the breakwater the frames are kept parallel by the sliding ties, which are simply balks of timber with chocks between them embracing two frames, and being secured together above water, they are slid down to the bottom. To obviate the employment of divers, the spaces between the frames, under low-water mark, are either filled with panels lowered from above, or by vertical pieces secured by the

sliding-ties, or by piling. These piles may be driven, or screwed, the sliding-tie forming a guide for the foot of each pile. In driving piles the author has placed the shoe on the corners of the piles which are exposed to the greatest pressure, and are most liable to abrasion. If screws are adopted, the author has designed an arrangement which, he thinks, would cost less than Mitchell's screws, and which is as follows:—The angles of the wood being removed, a thin T iron is heated, and wound spirally round the lower end, and this being cooled, shrinks and grasps the wood, like the tire of a wheel. The advantage of this plan is its cheapness, and the strain, instead of being concentrated, as in Mitchell's piles, upon the short piece of the pile embraced by the iron socket, is distributed over a considerable length of the balk.

It would be tedious to go further into detail upon such points. It may suffice to say, that no system of piling can be compared with the plan of first sinking frames, for cheapness and speed of execution, and in hard ground piles are inadmissible. The progress at Dover is said to be 100 feet per annum; and, as the breakwaters at Alderney, Portland, and Holyhead have each been about ten years in hand, the systems pursued at those places do not appear to secure rapid execution. In this particular it is thought a saving would be effected by the new arrangements; and as an illustration of what can be done, although of course on a comparatively small scale, it may be mentioned that of the Blyth work 130 lineal feet have been erected in five days.

POWER OF THE WORK TO RESIST WAVES.

It has been said that the timber-faced work cannot be breached and broken up in detail, that it must go as a whole—in fact, be overturned bodily; and it is now necessary to ascertain what amount of force would effect its destruction, which, unlike the case of most stone piers, is readily calculated. In the section designed for deep water, the power of the sea to overturn the work would be represented by the statical pressure of the water rising against the parapet, and the power of resistance in the work by the weight of the stone, less its displacement—the timber having no buoyancy. Proceeding upon this principle, and taking the 10 fathom section (Fig. 6) as an example, it is found that the stability is double the greatest force which could be brought to bear upon it.

It has been stated that waves travelling into shallow water must break, and in situations where it is necessary to provide a protection under these circumstances, a wave-screen, such as is represented in Figs. 8 and 9, is to be preferred. It will be observed that the screen consists mainly of a grating of timber, supported on piles, and inclined towards the sea, so that the waves will run up and the water will drop through the transverse openings, both on its ascent and descent, and little if any will return to the foot. In the case of a stone slope, the whole of the water which has been projected up the slope runs back, and it is by this recoil that the great damage is done. The dropping through of the water has another important advantage. Suppose the oscillation of the water passing under the toe of the screen to be only partially destroyed, the remaining motion cannot be more effectually combated than by the vertical and continued fall of water through the screen. Moreover, the effect of the blow of the waves upon the slope is diminished by the openings between the planks. There is, however, a limit to increasing these spaces, for if they are too wide the water falling through, instead of neutralising the existing oscillation would produce a fresh one. The longer the slope the greater the surface over which the force of a given wave is distributed, and the less the horizontal strain produced; but if the slopes were too flat, the effect would be that the wave would run up and fall over.

This wave-screen has a peculiarity which, in many situations, is of the greatest importance, —namely, the allowing the tide or currents of the sea to pass through with little interruption,

* A model of this arrangement was exhibited at the meeting.

BREAKWATER AT THE PORT OF BLYTH.

thereby preventing the silting-up of a bay, or the estuary of a river, which is a general consequence of its enclosure by any breakwater of an ordinary kind.

The construction of the screen is of the simplest kind. It consists of piles at considerable intervals. To these the main timbers are secured, upon which the grating of planks is laid. It will be observed that these planks are tapered in cross section, making the lower edge thinner than the upper edge. The object of this is threefold. First, it diminishes the shock of the water on the planks as it rises; secondly, it ensures the interception of the water on its descent; and thirdly, it gives to the main timbers a secure hold of every plank.

DURABILITY AND COST.

These two stand in such intimate relation to each other, that it is proposed to consider them together. The first question which arises is, how long will the timbers last? To this it is not easy to give a definite reply. The chief enemies to be encountered are the *Teredo Navalis*, or great worm, and the *Limnoria Terebrans*, or surface worm, as it is often called, but which, in fact, is a species of shrimp. The operations of the *Teredo* are said to be confined to the space between low-water and the bottom, as they cannot exist out of water, whilst the *Limnoria* attacks the wood chiefly near low-water, and particularly at the surface of the ground, in cases where the bottom is dry at low tide. There is no doubt that unprepared fir-timber, excepting the more resinous pines, would in some cases be destroyed in a few years by these animals, and it is said that even greenheart succumbs in time to their efforts; but there are instances which indicate great durability. The piers at Boulogne and at Calais may be mentioned as having stood for many years—a part of the latter, which is of oak, being above seventy years old. But the true question is with regard to the durability, not of raw, but of prepared timber; and the experience of the author of the process of creosoting leads to the belief that, when properly done, it will preserve timber for many years, though how long it is impossible to say, as time alone can show.

There is another material which the author is at present testing, but a sufficient period has not elapsed to prove its qualities. The author is of opinion, that there can be little doubt that the timber would last twenty years; but, without speculating further upon this point, it will be sufficient to show, that the difference in first cost between ordinary stone breakwaters and the new arrangement, is so great as to leave an ample margin in favour of the timber system. The 10-fathom section, Fig. 6, would cost, complete, about £70 per lineal foot; whereas the stone breakwater at Alderney is said to have cost £190 per foot, and that at Portland £150 per foot. The cost of these, as compared with the timber system, for a length of say 2,000 yards,—about the length of Portland and Holyhead,—would stand as follows:—

Timber System, Fig. 6	£420,000
Portland	900,000
Holyhead, unknown, but believed to have cost a great deal more.	
Alderney	1,140,000

The manner in which the timber of such a work, as is shown in Fig. 6, would be renewed, would depend on the nature of the bottom. If it was clay, or sand, for instance, the face might be simply close piled, and by the application of the new arrangements for piling, this would not be an expensive operation. But if the bottom were hard, then a cradle filled with stone might be lowered and thus the face would be renewed. This cage, as it may be called, would have several hundred tons of stone in it, and this would represent the weight of the smallest pieces of the face.

Finally, it remains to be shown, that even if the new arrangements be regarded merely as a means for forming the back-bone, as it were, of a more permanent stone structure, it is the best and cheapest way of attaining that object; for, viewing the timber only in the light of a temporary staging, the following would be some of the advantages of the system—rapidity of execution; the enclosure of the harbour, and the protection to the shipping being completed years before an ordinary stone-work could be erected; and an excellent staging from which to build the stone

facing, which might be proceeding at several places at once, as there would be no interference from the current, and no danger of breaching. Then the rubble hearting, having been exposed to the sea for years, would be thoroughly consolidated, and would form an impenetrable backing, which is always of great importance, and from the strength of the staging very large blocks might be employed in the facing.

(To be continued.)

FRENCH PRIZES FOR REAPING MACHINES.

PARIS, Friday July 23.—The competition for the prize proclaimed for the best reaping machine came off yesterday at Fougillouse. The Emperor was present, and exhibited the greatest interest in the proceedings. Forty-five machines had been registered, but twenty-five only appeared in the field. A wide extent of harvest land had been divided in patches of wheat, rye, and barley—all nearly in equal proportion. The cutting of each patch was drawn for by lot. The machines were catalogued under two distinct heads—the foreign machines and those of French manufacture. The prizes for each division were the same—1,000 fr. and a gold medal first prize, 500 fr. and a silver medal the second, 300 fr. and a bronze medal the third. Moreover, a great gold medal had been voted as honorary prize to the machine considered the best of the whole, whether French or foreign. This prize, as well as the first in the foreign division, fell to the lot of Messrs. Burgess and Key. Worked by two horses, its action surprised the assembly. The harvest fell before it with a precision and regularity never attained by human hand, while the quickness with which the work was executed proved an incontestable superiority over manual labour. Moreover, this machine proved itself the only one in the field capable of being worked with the assistance of only one man, and by measurement it was known that the Burgess and Key reaper could clear an hectare of ground in an hour and a half. Cranston, of London, obtained the second foreign prize. The first French prize was awarded to M. Mazle, of the Department of the Orne, the second to M.

DUNCAN AND GWYNNE'S PATENT HEAT DIFFUSERS.

Longitudinal section of part of a tubular boiler, with three varieties of spiral heat diffusers, shown within the tubes, the central tube has a ferrule inserted.

C represents the spiral with holes cut through the plate, which is of some advantage with a short pitch spiral.
D represents a spiral with a long pitch, most suitable where the fuel is bituminous, or the draught sluggish as in marine engines.
B represents a short pitch spiral for boilers where the draught is strong, or the fuel coke as in locomotives.

Lallier, of the Aisne, and the third to M. Legendre, of the Charente Inferieure. Independently of these testimonies to physical perseverance, another prize of more importance still was voted to M. Durand, Mayor of Baruel, for the moral perseverance with which, in spite of the opposition of ignorance, he had encouraged the use of the machine in his commune, and a silver medal and a sum of 100*fr.* were likewise awarded to the ploughman in the employ of M. Durand, for having aided his master in this undertaking. The Emperor was accompanied on the ground by the Count de Montebello, where he was received by M. Rouher, Minister of Agriculture, by Count Chasseloup-Laubat, Minister of Algeria and the Colonies, and by all the notabilities connected with the progress of agriculture in France. At the close of the experiments the Emperor presented to each of the successful candidates the prize which had been awarded him, and at six o'clock left the field amid the hearty plaudits of the assembly.—*Correspondent of "Morning Star."*

DUNCAN AND GWYNNE'S PATENT HEAT DIFFUSERS.

AN invention has recently been introduced whereby the steam-producing power of engines may be greatly increased. This is done by introducing into the tubes of boilers spiral heat-diffusers. By the aid of these diffusers a column of heated gas is so distributed in the tube of the boiler as to make it produce, it is said, about 30 per cent. more steam. Flames and other gaseous products of combustion in passing through the tubes of boilers now in use, impart only a portion of their heat to the surrounding metal. These productions pass with considerable rapidity through the tubes, and being aeriform and bad conductors, consequently a large proportion of their energy is unproductively expended by the present mode of generating steam. The metal of the tube only absorbs heat from that portion of the column of flame in direct contact with it, consequently, the central portions of the column are permitted to escape with the smoke out of the chimney. The patent heat-diffusers now under notice break up this column, and compel its component particles to strike against all sides of the tube. In this way more heat is transmitted to the water of the boiler, and consequently, more steam produced at a less cost.

The advantages of these heat-diffusers are obvious and manifold. In the first place they are very simple, and their application does not require any alteration of the boilers now in use; and they can be inserted at the shortest notice at a comparatively small cost. Secondly, it has been proved by experiment that they are self-cleansing. Thirdly, they materially lessen the consumption of fuel. This is their characteristic advantage, and will in all probability recommend them to the consideration of engineers, railway and other companies.

Upon the 9,500 miles of British railway there are now employed more than 5,000 locomotives, performing an annual mileage of upwards of 90,000,000 miles. The fuel consumed by these engines may be taken as equal to 1,500,000 tons of coke; and this quantity of fuel may be valued at £1,200,000. The introduction of the heat-diffusers to the above number of locomotive boilers would effect, at 30 per cent., an annual saving of £400,000, and involve no alteration in any of the existing arrangements.

No doubt this invention will be found particularly valuable to steam navigation. A full-powered 3,000 tons paddle steamer carries 550 tons of engines, boilers, and appurtenances, 1,400 tons of coal, and 100 tons of water in her boilers, making nearly two-thirds of her burden. It is principally on account of this vast tonnage of fuel that steam navigation has hitherto proved a commercial failure—as it is well known that no line of swift steamers can exist without a Government mail contract. If, however, a steamer which has hitherto required 1,400 tons of coal may, by the aid of the heat-diffusers, perform her voyage with less than 1,000 tons, a vast saving will be realised. Supposing the coals to cost £1 per ton, there would not only be the saving of £400, but there would be 466 tons of freight space, amounting, on a rough calculation, to £1,350, at the rate of one farthing a ton per mile, being £1,700 upon a single voyage to New York, or £3,400 on a voyage there and back, which is more than equal to the Government subsidy now granted to each large mail steamer.

We may add that the patent heat-diffusers are manufactured and supplied by Gwynne and Co., Essex Wharves, Strand.

WARD'S AMERICAN SHIP SIGNALS.

Mr. W. H. Ward, of Auburn, United States of America, yesterday exhibited in Woolwich Dockyard, by permission of the Lords of the Admiralty, his patent invention for transmitting messages and carrying on correspondence of any length from ship to ship, becalmed, or sailing within telescopic sight of each other on the ocean, with equal facility to that of the electric telegraph on land. The exhibition was witnessed by Commodore

the Hon. James R. Drummond, C.B., Aide-de-Camp to the Queen, in his official capacity as superintendent, attended by the entire body of officers representing the various departments of the yard. One of the instruments was erected at either end of a long enclosed lobby adjoining the dockyard factory, when a lengthened test of messages and replies was satisfactorily carried out. The experiment was extremely interesting and conclusive as to the merits of the apparatus, the result of which was promptly transmitted to Lord Clarence Paget by special direction of the Commodore to that effect, the invention having been pronounced one of the most important of the kind hitherto produced, and likely to be productive of immense benefit to the entire naval and merchant service afloat. The weight of the instrument, which is of the simplest construction, does not appear to exceed 14lb. It represents the form of a cross, exhibiting five alphabetically marked lamps, which are worked by a process resembling the keys or notes of a piano slowly depressed, and at the termination of each sentence the lights are clouded. As regards the working of the instrument, the principal officers of the Flagstaff who yesterday attended the experiments affirmed without hesitation that any boy of Her Majesty's fleet could obtain a perfect mastery of the system by a couple of evenings' study.—*Naval Intelligence of the "Times."*

THE MANUFACTURE OF CANNON.

(Concluded from p. 58.)

MR. LONGRIDGE next made a gun of a thin cast-iron tube, with wire coiled round it. It weighed only 3 cwt., yet threw a 9-pound shot 1,500 yards.

A 6-inch hydraulic press, which he had made of cast-iron three-quarters of an inch thick, with wire coiled round it with a carefully-calculated increasing strain to a thickness of half an inch, was sent to a gentleman at Glasgow to be tested; he reports that it has borne a pressure of upwards of seventeen tons per inch! One-fourth of this would have destroyed most cast-iron cylinders of treble the thickness.

Time, I regret, will not permit me to describe any other of Mr. Longridge's valuable experiments. I will only mention one more experiment to-day, but that a most important one, because made by Colonel Treuille de Beaulieu, a distinguished French artillery officer, and one of the *Comité d'Artillerie* of France. He had a 32-pounder (French 30-pounder) turned down cylindrical from the breech to near the trunnions. Over this he shrunk steel tubes, accurately bored.

At first sight this looks very like my plan, but I regret to say that I cannot quite agree with Colonel Treuille in his method of construction.

The steel he uses is very tough, and similar to that wonderful metal now made so inexpensively

by the Mersey Steel Company. Like it, it can be stretched one-fifteenth of its length without breaking, and one one-hundredth-and-fiftieth without losing its elasticity. Colonel Treuille made his outer tubes only one three-hundredth of their diameter less than the outside of the cast-iron cylinder. This was about $16\frac{1}{4}$ English inches in diameter; the bore of the gun being about $6\frac{1}{2}$ inches. Now this cast-iron cylinder is thicker in proportion to its bore than any of those Major Wade tried. The outsides of his were stretched but one-eighth as much as the inside, *when free to expand*. I do not think that in Colonel Treuille's 32-pounder, therefore, the outside of the cast-iron cylinder, encompassed by a strong steel envelope, can expand more than one-tenth as much as the inside of the gun. Granting, even, that his cast iron can be stretched 1 in 300 without danger (which I doubt), still the outside would only be increased, even then, 1 in 3,000. One three-hundredth added to one three-thousandth would then be the greatest elongation of the steel possible, without fracturing the inside of the cast iron. Nearly one-half of the strength of the steel is thus made no use of.

As it is, the gun is strong enough to resist any strain by gunpowder in a lateral direction. When Colonel Treuille first showed and explained it to me, I ventured to express an opinion that the breech would eventually be blown back, owing to the great squareness of the end of the bore in French guns. I had the honour of seeing that gentleman, however, a fortnight ago, and was rejoiced to find, as I am sure you will all be glad to hear, that hitherto neither this nor any other catastrophe has occurred. On the contrary, the gun has borne 1,000 proof-charges without the slightest injury except to the vent, which, of course, has been more than once renewed.

Although I think that Colonel Treuille could have obtained equal strength by the use of one-half the quantity of steel, had he made the steel cylinders one four-hundredth part less in diameter, still, as he actually does not make them do ten times as much work as if they were not in a constant state of tension, I hope I may fairly consider him as an authority, and a most weighty one, in favour of the principle of construction I am advocating.

His method of manufacture must not be confounded with that proposed years ago by General Thierry, who thought to obtain the rigidity of cast iron and the strength of wrought iron by simply placing tubes of the latter metal over one of the former metal. Guns were so made, which looked exactly like Colonel Treuille's or mine; yet they were perfect failures. The reason is obvious; the strain was not communicated to the wrought iron, as it had no initial tension, or at most only enough to give it a firm hold on the interior.

The difference of opinion between Colonel Treuille and myself is only as to the degree of disproportion between the useful effect of the inside and the outside of cylinders. He thinks that in the 32-pounder he made, the outside of the cast-iron part, which was about 50 inches in circumference, could exert two-fifths as much strength as the inside, which was about 20 inches in circumference; the diminution being in the direct proportion of the diameter. Now, I believe that the diminution is in a greater ratio than even the squares of the diameters; in the above case more than 25 to 4, instead of 5 to 2.

The question is of such importance in deciding the necessity of abandoning the present method of making guns by casting, that I trust you will permit me to discuss it a little fully.

Those who, like Colonel Treuille, argue that the strain is in the inverse ratio of the diameter, must believe that the thickness of metal remains constant whatever the pressure; for under no other conditions would one part be exactly as much elongated as another. Even on this view of the case the outside of a service-gun, which is fully three times greater in circumference than the inside, could only do one-third as much work, because an elongation which would strain a fibre

of one length to a certain amount, could only strain a fibre three times as long one-third as much.

I have already given reasons why the metal must decrease in thickness when strained; I will now, therefore, only refer to Major Wade's experiments, which show that in every instance he tried such was the case.

Those who argue that the strain is in the inverse ratio of the squares of the diameters, believe that the thickness of the metal diminishes as the circumference is increased by pressure from within, but that the total bulk of the metal remains constant; and that, therefore, the area of the surface of metal, which would be exposed by making a cross-section through the cylinder, perpendicular to its axis, must be also constant whatever the pressure. Now, on this hypothesis even, the outside of a cast gun could not do more than one-ninth of its work; *yet, in all Major Wade's experiments, the cross-section was decreased by strain up to a certain point, which proves that the useful effect of the metal must have decreased in a greater proportion than even the squares of the distance from the centre.*

Had I not found an account of these experiments I should have despaired of ever convincing any but persons possessing a knowledge of science that guns are at the present time being cast by thousands in such a manner that fully two-thirds of the metal in them is not only utterly useless but most mischievous, because rendering their transport more difficult and expensive; and that the extreme outsides of the present guns cannot exert one-twelfth of the power they could be made to exert.

These experiments are valuable to me also as establishing the truth of another argument I used here on a former occasion. It is constantly asserted that the pressure of the gas of gunpowder amounts to ten or twelve tons per square inch of surface, and that its action being sudden is more mischievous than an equal pressure applied more slowly. As guns do bear the repeated application of this pressure, I was told that I must exaggerate their weakness. My reply was, that the shot, by moving directly the first particles of powder burnt, leaves room for the rest to expand gradually, and that the pressure can never be so great as is said, because such pressure acting through a certain space must necessarily produce a greater velocity than we know is produced. The belief in the great pressure of the products of powder, which has been handed down to us from former generations, must now at last yield to demonstration. Major Wade burst a serviceable 18-pounder gun behind the trunnions with a pressure of $4\frac{1}{2}$ tons per inch. The pressure of the gunpowder must therefore have been less than $4\frac{1}{2}$ tons per inch, or at all events less destructive than that pressure longer applied. This is very important, upsetting all preconceived ideas of the violence of the explosion of gunpowder in the cannon now used. In larger guns the pressure of course would be greater, because the shot would acquire motion more slowly, therefore would leave less room for the igniting powder. Hence the larger the gun the greater the difficulty of getting it to resist the explosion; hence the utter impossibility of making guns beyond a certain size to fire full charges of powder without making more than one layer of metal take its fair share of work.

In rifled cannon this limit is reached in a smaller calibre than in smooth bores, because the resistance of the twist and of the friction prevents the shot moving from its place rapidly enough to leave room for the gas of the powder, which being thus confined exerts more power.* This additional power has been turned to advantage by Mr. Armstrong, but has hitherto baffled Mr. Whitworth, in his endeavours to obtain good results from rifled cannon. The 32-pounder and the 68-pounder made by the latter were burst by the pressure in the gun, though the shot was of iron only, and not tightly fitting. Mr. Armstrong's

* This was written, it should be recollected, in January last.—Edw. M.M.

guns, on the other hand, bear without injury the much greater pressure resulting from the use of a bullet covered with lead, and fitting extremely tight. His bullets, indeed, are made larger than the general bore of the gun, are inserted at the breech end, where the barrel is slightly wider, and are forced by the gas of the powder through the narrower part. The pressure of this gas must be enormous, because the powder must have time to be entirely burnt before the shot moves many inches, resisted as it is.

How, then, does Mr. Armstrong obtain power, accuracy, great velocity, and extreme range from a pressure much greater than that which destroys Mr. Whitworth's guns? How can he use a pressure capable of giving such velocity to his bullets, that a twist not half so rapid as Mr. Whitworth uses is yet sufficient to ensure accuracy which must be seen to be credited?

I will answer these questions by quoting the words in which Captain Younghusband, R.A., described the manufacture of Mr. Armstrong's guns to the Royal Artillery Institution in April, 1856:—

"A core, or internal lining for the gun, was formed of cast steel, to which the requisite strength was given by encircling it with twisted cylinders of wrought iron, made in a similar manner to gun barrels, and tightly contracted upon the steel core by the usual process of cooling after previous expansion by heat; the parts are then in that state of initial tension which is necessary to bring their entire strength into operation."

This "initial tension" of the outside of the guns is, then, the difference between Mr. Whitworth's and Mr. Armstrong's, between failure and unexampled success; and it is this "initial tension" of the outer parts which I have been advocating for upwards of four years, which I have endeavoured to advocate to-day, as not only beneficial but absolutely necessary when great strength is required.

It is but fair to Mr. Armstrong to state, that, judging from dates, his first gun must have been commenced long before I published my views, although after I had taken a patent and made one or two guns. We, therefore, arrived independently at the same conclusion.

Though I claim to share with him the honour of the invention of the means of obtaining strength in cannon, yet the marvellous accuracy he attains, the ingenuity and simplicity of his plan for loading by the breech, the perfection of his fuse, the skilful shaping of his shell and of the inside of his barrel, the scientific way in which he secures the great pressure, guarding against any waste of it; these and many other advantages are due to him and to him only (so far as I know), and I am confident you will all join me in hoping he may receive the hearty gratitude of his country for his patient, laborious, most scientific, and most successful researches.

I will conclude by taking the liberty of entreating any of you whom I have been able to convince of the truth of my views to promulgate them. I venture to make this request now, because every cannon foundry in the kingdom is busy making guns which in a year or two must be obsolete; and because, what is far more dangerous, we are planning expensive means of defending our seaports against guns now in use, against guns which we will heed no more than bows and arrows by the time our defences against them are completed. Those defences I need hardly say will be useless against cannon which can be made, and which in a year or two will be made.

TOWERS OF STRENGTH.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—All soldiers who have been engaged in "various wars" know that the first object of an active enemy is to rush at and seize upon strong buildings, such as churches, mills, factories, &c., and immediately set to work in fortifying them in such a manner as to cause great loss to those who would endeavour to retake them. All our churches are strong buildings, generally fortified with towers. In the event of

invasion, I would defend such buildings with my frictional grenades, which can be made to explode with unerring certainty within five or six feet of the ground, whatever height the building may be of, high church or low.

This frictional grenade formed one of the many practical experiments I recently made at Chatham with the sanction of his Royal Highness the Commander-in-Chief, and the late Secretary of State for War. Captain Lemprière, R.E., who superintended the experiments, reported of the frictional grenades that they answered admirably. Having obtained permission from Mr. Jones, proprietor of the far-famed Rosherville Gardens, I shall with great pleasure show the manner of using my grenades to all persons wishing to understand it, as well as other experiments, such as were practically demonstrated at Chatham; Mr. Lock, the instructor of rifle practice on the grounds, will assist me in the course of the experiments. I am, your obedient servant,

J. NORTON.

Rosherville, 25th July.

BOAT-LOWERING APPARATUS.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—As Mr. Clifford is inclined to rate you for the publication in your Magazine of a statement made by some anonymous and untruthful individual, having reference to what he terms the *alleged* loss of a boat's crew of Green's ship *Orwell*, I can do no less than furnish you, for your own special information, with the source from which the original statement is derived, backed up with two other documents which further tend to confirm its truth.

The rank and position held by the original informant, you will admit, render his authority unquestionable, while the matter of the documents herewith enclosed being entirely derived from Mr. Clifford's immediate supporters, are not to be objected to, on his side at any rate. The first of these witnesses states that although assured of the truth of the *Orwell's* deplorable disaster by Mr. Green's officers themselves, that the fault which occasioned it was attributed to the "*lowering man*," and that no blame was attached to the apparatus itself. The second, you will observe, is silent altogether as to the cause of the catastrophe, but dwells on the fact of *two* only of the boat's crew having been drowned, the remaining two having died subsequently through want of food and exposure to a *snow-storm* (a condition of the atmosphere, one would imagine, fatal to the safe working of Mr. Clifford's pendants and nip-sheaves). Be it as it may, these two versions of the affair do not by any means tend to remove the veil of mystery which hangs about it, and it is to be regretted, therefore, that Mr. Clifford, professing as he does to work for the public good, confines the terms of that part of his last letter to a short phrase of exoneration of his plan on the part of Messrs. Green and the master of the *Orwell*, leaving the public totally in the dark in those points of detail on which the latter would necessarily desire to be informed. By leaving the matter thus in its incomplete shape, would seem to offer a parallel, as far as the public curiosity is concerned, to the testimonial afforded by some imaginary proprietor of a coal mine to disaster of another sort, which we will suppose, for the sake of illustration, to run thus:—

"DEAR SIR,—With reference to your note just received, I beg to inform you that the explosion of fire-damp in the mine of which I am the proprietor, which caused the melancholy loss of all the workmen engaged in it at the time, is not attributable to the Patent Safety Lamp of your invention, which they carried in their hands, and no blame whatever can be attached to that valuable invention. "I am, &c., &c."

The remainder of Mr. Clifford's letter is not remarkable for its accuracy, more especially in that passage where he arrogates to his invention the merit of *standing alone* in the great cause of saving human life; he must be well aware (indeed

the public in general, for the fact went the round of the public journals), that the captain of the *Euryalus*, (the second ship supplied with Captain Kynaston's life-hooks), bears record to the fact of a seaman's life being saved by this method under somewhat difficult circumstances.

It seems, moreover, that Mr. Clifford's frequently expressed desire of competitive trials being ordered between the two methods, has been always forestalled, and that trials are in progress, and, as far as I can glean, more especially in the case of the *Exmouth* and *Topaze*, that these trials have not been favourable to Mr. Clifford.

The test of time, and changes of the atmosphere, I may observe, are the chief enemies to Mr. Clifford's arrangements; and surely as a naval officer of some practical experience and long sea service, I may hardly with reason be accused of preaching mere vague theories to a person of an opposite calling, who although he may have invented an ingenious plan for lowering boats, and has frequently been lowered in them himself, can have no experience in the ever-varying changes of a ship's voyage, and the means of adapting any part of our naval economy—management of boats included—to meet them. I remain, Gentlemen,

Your obedient servant,

NAUTICUS.

July 24th, 1859.

[Complaint has been made to the effect that it is unfair to Mr. Clifford to permit this boat-lowering controversy to be pursued on one side by an anonymous correspondent. It is said that while Mr. Clifford is made rigidly responsible for every word he utters, his opponent is practically irresponsible, and cannot be made to suffer the just recompense of any inaccurate statements which he may please to make. Readers must be aware that the question thus raised is both a delicate and a serious one. On the one hand, we cannot for a moment admit that there is any unfairness in anonymous correspondence itself; nor can we undertake to debar ourselves from inserting the communications of those gentlemen who, from holding high offices, or from other causes, are precluded from using their name in public controversies. On the other hand, we readily acknowledge that when questions of fact, of momentous importance to one of the disputants, are raised, as they have been in the present dispute, there is some risk of the anonymous writer exposing the other to an ordeal to which he would himself object. Consequently, after deliberation, we have decided that it will be better to bring the present discussion to an end. We have all confidence in the integrity of "Nauticus," and our readers have had ample proof of his ability; but notwithstanding these things, we think full justice to Mr. Clifford requires that the grave questions of fact which have been raised should not be further discussed by a gentleman whose position imposes anonymousness upon him. The resolution we have come to in this matter must be attributed solely to the nature of the subjects discussed; we would never for a moment think even of forcibly closing a purely argumentative discussion on the grounds just stated. At a future time "Nauticus" will, we trust, be relieved from his present restraint.—Eds. M. M.]

NOTICES.

The *MECHANICS' MAGAZINE* will be sent free by post to all subscribers of £1 ls. 8d., annually, payable in advance. Post Office Orders to be made payable to R. A. Brooman, at the Post Office, Fleet Street, London, E.C.

TO ADVERTISERS.

All Advertisements occupying less than half-a-column are charged at the rate of 5d. per line for any number of insertions less than 13; for 13 insertions, 4d. per line; and for 52 insertions, 3d. per line.

Each line consists of 10 words, the first line counting as two. Wood-cuts are charged at the same rate as type for the space occupied.

Special Arrangements for larger or Serial Advertisements. To ensure insertion, Advertisements must reach the Office by 5 o'clock on Thursday evening each week. None can be received after that time for the ensuing number.

Our Weekly Gossip.

THE Commission, consisting of Professors Faraday, Hofmann, and Tyndall, Mr. R. Redgrave, R.A., and Capt. Fowke, R.E.,—appointed for the purpose of reporting to the Lords of the Committee of Privy Council on Education "On the lighting of picture galleries by gas, and on any precautions (if necessary) against the escape of gas, and the products of its combustion"—having met at various times and considered the subject referred to them, now make the following report:—There is nothing innate in coal gas which renders its application to the illumination of picture galleries objectionable. Its light, though not so white as that of the sun, is equally harmless; its radiant heat may be rendered innocuous by placing a sufficient distance between the gas jets and the pictures, while the heat of combustion may be rendered eminently serviceable in promoting ventilation. Coal gas may be free from sulphuretted hydrogen compounds, and in London is so at the present time; it then has little or no direct action on pictures. But it has not as yet been cleaned from sulphide of carbon, which, on combustion, yields sulphurous acid gas capable of producing 22½ grains of sulphuric acid per 100 cubic feet of present London coal gas. It is not safe to permit this product of the combustion to come in contact with pictures painted either in oil or water colours; and the Commission are emphatically of opinion that in every system of permanent gas lighting for picture or Sculpture galleries, provision should be made for the effectual exclusion or withdrawal of the products of combustion from the chambers containing the works of art. The Commission have examined the Sheepshanks' Gallery as an experimental attempt to light pictures with gas, and are of opinion that the process there carried out fulfils the condition of effectually illuminating the pictures and at the same time removing the products of combustion. According to the indications of the thermometer required and obtained, it does this in harmony with, and in aid of, the ventilation, and does not make a difference of more than one degree Fahrenheit at the parts where the pictures are placed, between the temperatures, before and after the gas is lighted. Certain colour tests consisting of surfaces covered with white lead, or with vegetable and mineral colours (especially the more fugitive ones), and in which also boiled linseed oil, magylyp, and copal varnish were employed as vehicles, had been prepared, and were, when dry, covered one fourth with mastic varnish, one fourth with glass, one fourth with both mastic varnish and glass, and one fourth left uncovered. Sixteen of these have been placed for nearly two years in different situations, in some of which gas has been used, in others not. They give no indications respecting the action of coal gas (except injury from heat in one placed purposely very near to and above the gas burners), but seven of them shew signs of chemical change in the whites, due to either a town atmosphere or want of ventilation. The most injured is that from the National Gallery, Charing Cross, and the next is from a country privy; the third much less changed is from the House of Commons; the fourth is from the Barber Surgeons' Hall; the fifth from the Bridgewater Gallery; the sixth from the Royal Society's Rooms, Burlington House; the seventh from the British Museum. The remaining tests hung in:—1. Sheepshanks' Gallery, South Kensington. 2. Secretary's Room at South Kensington, where no gas is used. 3. Mr. Henry Drummond's Drawing-room at Albury Park, Surrey. 4. Sealed up and kept in a closet in the Secretary's Room at South Kensington. 5. Lambeth Palace, Vestibule of the Staircase. 6. British Institution, Picture Gallery. 7. Windsor Castle, room with a north aspect without gas. 8. Mr. Thomas Baring's Picture Gallery, 41 Upper Grosvenor-street, frequently lit with gas—present no observable change in this respect. Though apart from the especial subject submitted to the Commission the Members cannot resist a recommendation that this kind of trial, which is especially a painter's experiment, should be continued for a longer period, and, indeed, be carried out on a more extensive scale. The Commission think it right to state that they were unanimous on all points to which their attention had been called, or which are referred to in this report.

A correspondent, a "Civilian," writes:—"In reading your article this week on the subject of rifled guns, it has struck me that what we want for immediate use is a rifled ball that can be applied at once to our smooth-bored artillery, not only in the navy, but all over the world. I should imagine (and would lay the case before inventors of warlike instruments for their consideration) that an elongated ball, with three or four spiral grooves cut into it, would by the action

of the exploding powder be made to rotate, and in very many respects resemble in its action a ball shot from a rifled cannon, and that smooth-bored guns furnished with such balls would partake very much of the quality of rifles."

A practical shipbuilding friend sends us the following useful memorandum:—"You are aware that yellow metal sheathing has recently failed to an extraordinary extent. It has been very usual to discover indications of galvanic action between the nail heads and the sheet metal. In the sample I send you herewith, it appears that the nail head, on the contrary, has preserved the sheet; and if you break the part of the sheet which is left in the reticulated state of the piece sent all over the ship's bottom, the fracture appears to be rather that of copper than of yellow metal; as if the zinc had been decomposed and the copper of the yellow metal composition left." The specimen forwarded entirely bears out these statements.

The following needs no introduction:—"Sidmouth, July 20, 1859. Gentlemen,—May I take the liberty to draw your attention to a little circumstance connected with the Electro Magnetic Coil. I some time since fitted myself up a machine according to directions as given by Bentley in the MECHANICS' MAGAZINE, No. 1769, for July 1st, 1857, with the exception of my primary wire being stouter than those recommended, No. 101, 30 yards long, instead of No. 14, with a condenser of about 130 series, 6 by 12, formed with stout writing paper, enclosed between two sheets of thin gutta-percha, so that the tin foil may be thoroughly insulated; my secondary wire is about two miles in length, No. 35. I find by applying a graphite battery of 12 pair of plates, $3\frac{1}{2}$ by 6 in., gives a very smart spark and very rapid; but if I take one of the pairs of plates and use 11 as a battery, and apply the poles of the remaining one to the poles of the former, connecting the zinc poles with each other, as also the graphite poles, the power is increased to a surprising degree, the magnetism in the core being increased three fold, and the spark at the terminals of the secondary wire proportionably exalted. Not having seen the circumstance mentioned, I am not aware if the fact has been before discovered. Perhaps some of your numerous correspondents who might have a similar apparatus would be kind enough to try the experiment, and give the result through the MECHANICS' MAGAZINE. Yours respectfully, S. CHICK.—P.S. I find the same proportionate amount of power in a less number of plates, say 6 pair with the extra plate. The magnetism being so much increased, would it not prove a very superior arrangement for the magnetic engine. I have not had time to vary the number of plates in the secondary battery; probably a still greater power would be obtained by a series.—S. C.

Viscount Carlingford writes:—"To the Editors of the MECHANICS' MAGAZINE. Gentlemen,—Allow me to trouble you with the reply I forwarded to *The Engineer*, in answer to a letter addressed to you, therein inserted; your obedient servant, CARLINGFORD." "To the Editor of the *Engineer*. Sir,—In reply to the letter of Mr. Robert Griffiths, in your last number, I trust you will allow me to inform him through your paper, that so far from claiming to be the inventor of his patent screw propeller, he will find on referring a second time to my two letters, published in the MECHANICS' MAGAZINE, that I have condemned its principle as regards its adjustable pitch. But let me inquire of him the reason he takes a new patent for that which he states he took a patent for ten years ago, while only five years ago the Admiralty had condemned all screw propellers then in existence, so much so that Government had ordered that no vessel worked by the screw should be employed to carry Her Majesty's mails? Then is it not clear that Mr. Griffiths has applied the pitch of the Carlingford screw to his old patented screw propeller, and now takes a new patent in the hopes of making the public believe that he is the inventor or discoverer of the new principle, which I alone discovered, and which alone gives to his screw propeller its new qualities. I trust the Admiralty will now see the propriety of giving the screw I presented to them and the country its proper name of the Carlingford Screw, and not insist further on calling it the Admiralty Screw—for none at the Admiralty had anything whatever to do with its discovery—and so put a stop to all persons in future attempting to take on themselves the merit of the real discovery by merely making some trivial alteration to some part of it which had nothing whatever to do with its principle, and then call it a new invention of their own. I might as well bore holes in the chimney of a locomotive, and, taking a patent for it, call the entire my own invention. I remain, Sir, your obedient servant, CARLINGFORD. Swift's Heath, 18th July, 1859."

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgement:—

STEAM ENGINES, &c., 2830, 2837, 2858.
BOILERS AND THEIR FURNACES, 2838, 2847, 2866.
ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 2853.
SHIPS AND BOATS, including their fittings, 2823, 2844.
CULTIVATION OF THE SOIL, including agricultural and horticultural implements and machines, 2828.
FOOD AND BEVERAGES, including apparatus for preparing food for men and animals, 2865.
FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 2833, 2845, 2849, 2850, 2862, 2867.
BUILDINGS AND BUILDING MATERIALS, including sewers, drain-pipes, brick and tile machines, &c., 2822, 2834, 2837, 2840, 2846.
LIGHTING, HEATING, AND VENTILATING, 2824, 2837, 2848, 2844, 2846, 2854.
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 2819, 2820, 2823, 2826, 2827, 2829, 2811, 2842, 2852, 2854.
METALS, including apparatus for their manufacture, 2831, 2847, 2859.
CHEMISTRY AND PHOTOGRAPHY, 2820.
ELECTRICAL APPARATUS, 2835, 2836, 2864.
WARFARE. *None*.
LETTER PRESS PRINTING &c. *None*.
MISCELLANEOUS, 2830, 2832, 2834, 2839, 2848, 2851, 2853, 2855, 2856, 2860, 2861, 2863.

2810. G. F. CHANTRELL. "Improvements in apparatus applicable to the manufacture and revivification of animal or vegetable charcoal." Dated December 8, 1858.

This relates to apparatuses patented on the 17th October, 1853, and 8th June, 1855, and consists, 1, in causing an agitation in the char during the time it is being passed down through narrow retort chambers, in which it is being burnt. This is accomplished by forming the inner surfaces of the retort chambers corrugated, the hollows and rounds of which corrugations by preference should run horizontally. 2. In forming of corrugated metal the corrugated coolers into which the char falls after having been acted upon in the retort chambers. The object of the patentee in forming the coolers of corrugated metal is to obtain a greater amount of surface, and in the construction of it lighter sheets of metal may be used. He prefers in this case that the hollows and rounds forming the corrugations should run in a vertical direction. 3. In forming the upper parts of the pipes or passages which connect the bottoms of the retort chamber with the coolers of as great a horizontal sectional area as the retort chambers for a given distance below the bed-plates upon which the furnaces and char chambers are built. The communication pipes are then divided into two barrels, so that one-half of the char will run into the right hand cooler, and the other half into the left hand cooler, two coolers being used in conjunction with each chamber. 4. In forming on or fixing to the under side of the bed-plates, at the bottoms of one or more sets of the char chambers, a hump of iron, perforated with six hopper-mouthed holes for the passage of the char. The holes in the iron humps are carried down in an oblique direction on alternate sides for dividing the charcoal, so that it may fall into two coolers, suspended parallel to each other, below the vertical char chambers. *Patent completed.*

2811. C. DE CAPPOT and A. JARRIANT. "A new hydraulic counter." Dated December 8, 1858.

The patentees attach to the pipe from the main or other suitable supply a flanged pipe connected to a cock or tap, the pipe from which opens outwards at the bottom in the shape of a truncated cone, and is flanged at the bottom, so that it may be connected to a case enclosing a cylinder of gutta-percha, &c., having any suitable number of perforations, though the decimal ratio will be found preferable, the solid part of the cylinder being indented when necessary. The patentees connect to the aforesaid case a box communicating by a pipe with one of the holes of the gutta-percha cylinder, and also by another pipe to a bucket wheel, formed with any required number of buckets, starting from about the centre of the wheel, and sliding against the interior of the casing, at the bottom of which there is an aperture covered with wire gauze, &c. To the lower part of the case containing the gutta-percha cylinder, they connect a

pipe for giving the supply. They cause the shaft of the bucket to work any suitable gearing, having hands pointing to any number of dials, so that the exact quantity of the water passing through one hole of the gutta-percha cylinder can be measured, which sum multiplied by the number of holes in the said cylinder will give the amount of supply. *Patent abandoned.*

2812. R. L. P. MANNING. "A floating paddle-wheel." Dated December 8, 1858.

Here the inventor fixes two or more cylinders or drums to the sides of sailing vessels, making them of any suitable metal or material, and also watertight and air-tight, by which he increases the buoyancy of the vessel, and consequently its speed in sailing. For steam-vessels he gives the said cylinders or drums a rotary motion from the crank-shaft of the engine, or by other suitable means, and by attaching paddle-boards to the surfaces of the said cylinders or drums, either transversely or diagonally, but the latter in preference, he obtains a very effectual and powerful means of propulsion. *Patent abandoned.*

2813. M. HENRY. "Improvements in twisting fibrous materials, and in machinery or apparatus employed therein." (A communication.) Dated December 8, 1858.

The patentee claims, 1. the mode of twisting fibrous materials by bringing threads or yarns on to a reel, roller, wheel, or spool from off a number of bobbins, arranged on the same rapidly revolving spindle, the twisted threads or yarns passing between a cylinder and a pressure plate, or between two twist-regulating rollers at the upper part, so that if desired they may be gassed, glossed, or dressed during the progress of the operation. 2. The general arrangement and combination of parts and mode of action of twisting apparatus, consisting of a spindle above, or at the end of which are situated a cylinder and pressure plate or two twist-regulating rollers, and which spindle carries two or more bobbins, so arranged that their threads or yarns may be united between the cylinder and pressure plate or between the regulating rollers. 3. The method of action or combination of parts of centrifugal self-acting stop or arrangement described, in which a thread guide held in place by the thread or yarn itself as it passes, is released when such thread or yarn happens to break, and is then thrown outward by the centrifugal action of the revolving or twisting appliance, and in which also the wheel roller or reel on which the thread is being wound is provided with a key or a bolt and a stud or stop, the former causing it to partake of the rotary motion of the shaft on which it is carried, but not preventing its being loose thereon when disconnected or disengaged by the stud or stop. 4. The application of centrifugal force for effecting the self-acting stoppage, throwing out of action or disconnecting of the twisting apparatus of throwing or twisting machinery. *Patent completed.*

2814. S. PHILLIPS. "Improvements in sliding window sashes, shutters, and doors." Dated December 8, 1858.

Here the inventor dispenses with the usual pulleys, lines, and weights employed for raising and lowering or sliding sashes, shutters, and doors, and substituting for the same a curved or bow-shaped spring, which is secured to the edge of the sash, so that in use the spring will be compressed between the sash and the sash-frame. At both ends of this spring are mounted small rollers partly toothed and partly plain, forming a ratchet, the ratchet part being furnished with a spring pawl attached to the long spring to prevent the revolution of the roller in more than one direction. These rollers which thus assist the raising of the sash by running smoothly up the sash-frame will in some measure retard its downward movement by being locked in that direction by the action of the ratchet and pawl, which will thus overcome the tendency of the sash to fall by its own weight. *Patent abandoned.*

2815. A. LAMB and W. A. SUMMERS. "Improved arrangements of apparatuses for super-heating steam." Dated December 8, 1858.

The object here is to divide the steam to be super-heated into as thin films or streams as may be in order to get the whole quantity composing such films or streams quickly, thoroughly, and economically super-heated. The steam is passed through thin channels or ways arranged cylindrically, spirally, or parallel to each other, or in any other suitable direction in the flues, smoke space, uptake, or chimney. The invention applies especially to those boilers known as "Lamb and Summers' Patent Flue Boilers," but is also applicable to other steam boilers. *Patent completed.*

2816. W. KING, jun. "Improvements in apparatus

for roasting coffee and other substances." Dated December 8, 1858.

Here the inventor forms the cylinder of wire gauze or metal net-work, or perforated plate, and through one of the axles or arms in which the cylinder rotates a sampling or testing tube is fitted, through which a sample of the berries may be taken during the roasting without stopping the cylinder for that purpose. *Patent abandoned.*

2817. C. M. WESTMACOT. "Improvements in the permanent way of railways." Dated December 8, 1858.

For fixing fish-plates to railway rails, rails to chairs and sleepers, chains to sleepers, and the separate parts of chairs or sleepers (in such as are made in more than one piece) the one to the other, the inventor employs screw bolts having heads at one end, and right-hand and left-hand screws cut on the other. The screw thread which is furthest from the head is formed in a part of the bolt which is smaller in diameter than the part on which the other thread is cut. These screw threads receive nuts which are screwed on in opposite directions, and of which one screws to lock the other; or the screw nearest the head is arranged to screw into a hole tapped in the fish-plate or rail, or other part to be secured. In the construction of permanent ways in which transverse sleepers and chairs are employed he places cushions of wood exterior of the chair, and on each side of it, so that the underside of the rail may rest on these cushions. In arranging the chairs for supporting the rails he makes the end of one of the jaws a detached piece, which drops in between the rail and the other part of the jaw, and is secured by a bolt passing through it and through the bottom of the chair, and it is of such a form as when in place to hold the rail without the use of a key. There are various modifications included. *Patent abandoned.*

2818. H. MEIDINGER. "Improvements in electric batteries." Dated December, 8, 1858.

This consists in arranging batteries on the principle of "Daniell's Constant Battery," as hereafter described, avoiding the use of a diaphragm, and protecting the zinc from being too rapidly touched by the sulphate of copper. For this purpose a large vessel of glass is fitted partly, say two-thirds, with a diluted solution of zinc, and another glass of half the height and diameter of the larger vessel is placed within it, standing in the solution. The second glass is covered on the inside with a copper plate to serve as the negative pole of the battery, and a copper wire is fixed to the plate. This wire is covered by a small glass tube, so as to protect it from the liquid through which it passes. The mouth of the exterior vessel is closed by a cock in which are two holes, one for holding a large and high glass tube, the other for holding a strip of amalgamated zinc. The former, closed at the lower end with a permeable fabric, is plunged into the small glass, and kept full of sulphate of copper. This forms a solution within the interior vessel, and the negative pole is thus constantly kept in contact with a solution of this salt. The zinc is immersed as far as possible from the small glass into the zinc solution. The battery thus constructed serves for a long time, the sulphate of copper never getting at the zinc. *Patent completed.*

2819. R. L. BURROWS and J. KNOWLES, jun. "Certain improvements in the construction of pianofortes and organs." Dated Dec. 8, 1858.

The object here is to elicit the sound of two notes simultaneously by the touch of one key. It consists in connecting each key (and its individual mechanism) to its corresponding unison key, or octave above or below, by means of a series of rectangular bell cranked levers, the ends of which act upon or strike a projection upon the ordinary "sticker," which is raised by each key, so that the action of each key struck is transferred to its octave above or below, and the two notes are struck and the octave sound produced simultaneously. *Patent completed.*

2820. J. BARROW, jun. "Improvements in the treatment of coal-gas tar, and of the oils obtained by the distillation of the same, and for the application of substances obtained thereby." Dated Dec. 9, 1858.

The patentee submits to the process of distillation in any convenient apparatus a mixture in suitable proportions of coal-gas tar and any one or more of the bodies known as the oxyde of amyl, the chloride of amyl, the hydride of amyl, the acetate of amyl, or the carbonate of amyl, with or without the addition of the hydrated oxides of ethyl or methyl or of bodies derived therefrom. There are various modifications included. *Patent completed.*

2821. H. MAUDSLAY. "Improved glass and other vitreous vessels." Dated Dec. 9, 1858.

This consists in applying sulphuric acid to the tools used when operating upon vitreous substances in the same manner as oil is usually employed in lubricating

the tools used when operating in a similar manner on metals. *Patent completed.*

2822. J. ECCLES. "Improvements in arrangements and machinery for preparing for the manufacture and for manufacturing clay and other plastic earths into bricks, tiles, pipes, and other articles formed of such materials." Dated Dec. 9, 1858.

The object of the first part of this invention is to prepare clay and other plastic earths direct from the bed ready to be moulded by machines acting on the principle of those known as "dry-clay machines," in which system the process of tempering or pugging the materials is unnecessary. The invention consists in drying the clay-earths by currents of hot or cold air, produced by mechanical means as follows: The clay-earth is passed through one or more pairs of rollers, which deliver it on to a travelling endless belt, apron, or lattice (upon which it may be broken up into small particles); this arrangement conveys the clay-earth to any suitable distance, and while in progress it is subjected to heat and to a current of hot or cold air, so that by the time the travelling arrangement has conveyed the material to its point of delivery it has been dried sufficiently to be ready for moulding into bricks, &c. It relates, 2, to apparatus for moulding articles by expressing plastic earths through moulding orifices, and consists in a method of securing the moulding cores so as to keep them more correctly in their places. This is accomplished by a stay or stays in addition to the usual means. *Patent completed.*

2823. H. BELL. "Improvements in musical instruments." Dated Dec. 9, 1858.

This relates to the improvements of the tone of violins and other musical instruments by the introduction or addition of a "bell harmonica." As applied to a violin, this consists of a flattened tube or elliptical chamber of glass placed in the interior of the body of the violin, the two ends of this glass piece being carried by two end blocks of wood. These blocks are supported by a light pole or bar of wood fastened to the ends of the instrument, and passing along the interior of the glass sheet. A bow-shaped bar of lancelwood is placed transversely across the body of the instrument above the glass shell to support a sound-post, the top of which carries the breast of the instrument. *Patent abandoned.*

2824. J. LITTLE. "Improvements in fire-grates and heating apparatus." Dated Dec. 9, 1858.

This relates, 1, to open fire-places such as are used for domestic purposes in the warming of apartments, and it consists under such modification of the attachment to the front of such fire-places or grates of vertical or horizontal radial plates of metal, as a means of obtaining a superior amount of effective and available heat, and for improving the draught. *Patent abandoned.*

2825. J. ELDER. "Improvements in paddle-wheels." Dated Dec. 9, 1858.

The patentee employs plates of steel or iron of a thickness proportioned to the unsupported surface of the float, and to the maximum pressure to which it may be subjected. He bevels the edges of these metal plates, giving them a suitable angle, so that when applied as floats they will, on entering and on leaving the water, present the minimum of the resistance due to the thickness of such floats. *Patent completed.*

2826. J. STEWART. "Improvements in the construction of the action of piano-fortes." Dated Dec. 9, 1858.

This consists in mounting the escapement button on the fly or hopper, and at such an inclination that just as it comes against the surface of the projection it is moving in a direction perpendicular to that surface. *Patent completed.*

2827. T. ALLEN. "Improvements in folding bedsteads." Dated Dec. 9, 1858.

The two side-rails are here by preference made of metal tubes. Each side-rail is made to fold by having one or more rule-joints formed thereto. The sacking is folded at its edges and sewn over the side-rails. Towards the ends of the side-rails and on the under sides thereof are projections to enter the sockets of the legs or supports. It is preferred to cast such projections of malleable cast-iron, in the form of T-pieces, so that two of the parts of the tube forming a side-rail may in each case fit on and be fixed to such T-piece. The two pairs of legs used for each bedstead are crossed, and have sockets at their upper ends to receive the projections on the under sides of the side-rails. The head frame is formed of metal and covered with canvas or other fabric, and it has a projection at each end which enters a hole in the side-rail. *Patent completed.*

2828. J. WILSON. "Improvements in machinery for tilling and cultivating land." Dated Dec. 9, 1858.

Here a chain or rope is employed which has an anchor or suitable fixing apparatus at each end so as

to hold the same fast at or near the headland towards which the tilling or cultivating implement is being moved. A suitable carriage, by preference on four wheels, is constructed so as to carry a chain wheel-drum or pulley, which receives motion from a steam-engine, which, with its boiler, is carried by the carriage. The ploughs or other implements are attached to and dragged by the carriage, and to prevent turning the carriage and implements at the end of each bout, two sets of ploughs or implements are employed, so that one set may be in and the other out of action at each bout. The chain used is conducted partly around the chain-wheel by guide-wheels, so that as the chain-wheel is caused to rotate, it will, on the carriage passing from one headland to the other, pick up and again deposit the chain; and the end of the chain from which the carriage is for the time being moving, will have its anchor or holding apparatus moved, so that in the next bout the carriage and implements will act on a fresh portion of the land. *Patent completed.*

2829. H. WILSON. "Improvements in the construction of pumps." Dated Dec. 9, 1858.

This consists in the introduction into pumps of a plate of brass or other metal to which are attached two or more suction pipes leading into different directions. On the other side of this plate another plate is ground air-tight, and is made to work either with a circular, semi-circular, or lateral motion; the sliding plate is perforated with one or more holes, so that when the holes in the sliding plate are opposite the holes in the stationary plate, the water or other fluid may be drawn by the action of the pump from one or more different sources as may be required. There are modifications included. *Patent completed.*

2830. E. L. PENSUERE. "Improvements in apparatus for driving or for drawing up piles by steam." Dated Dec. 9, 1858.

Here a framework of timber say 45 feet high, is furnished with a steam cylinder fitted up with a piston and hammer. This said cylinder has connected to its lid at opposite points two strong metal rods, and to the lower extremities of the said rods a casting is fixed, the same being provided with two right and left handed screws on which are placed two moveable jaws, by which it is proposed to embrace firmly the head of the pile. As the pile is drawn by elastic force of the steam, the steam cylinder follows the pile, and when driven sufficiently far, the jaws are released from the pile, and the cylinder raised by connecting a chain to the top thereof. This chain passes on to a barrel or drum placed on the platform of the machine and is worked by a small steam engine, so that for drawing piles out of the ground it is only necessary to fasten the before-mentioned jaws round the head of the pile, and then to wind the chain around the barrel, at the same time gently tapping the head of the pile with the hammer. *Patent completed.*

2831. B. LAUTH. "An improved mode of manufacturing rods and shafts." Dated Dec. 9, 1858.

Here the patentee takes the ordinary rolled rod of commerce of whatever size required (which is produced by passing the metal while red hot between grooved rolls) and immerses it in dilute acid to remove the scale therefrom. This immersion is not, however, required except when the article to be produced is intended to have a bright surface. When washed in water and dried he passes the cold rod between a pair of steel rolls formed with a series of grooves, which have the edges of the grooves rounded off to prevent ridges or lines being formed on the rod. The cold rolling is repeated as frequently as may be necessary, the rod being turned round as the rolling proceeds. *Patent completed.*

2832. J. BETHELL. "Improvements in machinery and apparatus for the preservation and colouring of wood." Dated Dec. 10, 1858.

This consists in protecting the iron cylinders used for preparing wood with chemical solutions from the action of acids by first lining the inside of the cylinders with sheet lead, caoutchouc, or gutta-percha; after the interior of a cylinder is so protected the inventor constructs another lining of wood. *Patent abandoned.*

2833. J. LIGHTFOOT. "Improvements in printing or staining yarns, fabrics, or fibrous substances, and in the manufacture of certain compounds for that purpose." Dated Dec. 10, 1858.

This consists in making an alkaline solution of colouring matters and metallic oxides, with which, when thickened, the patentee prints fabrics or yarns, putting the said fabrics afterwards through a subsequent process for developing and fixing the colour. *Patent completed.*

2834. J. FLOCKTON. "Improvements in stop or reversing taps." Dated Dec. 10, 1858.

For preventing the loss of time in working a series of hydraulic presses, the inventor employs a stop or

reversing tap, having a chamber with three apertures, one of which is connected to the supply pipe from the pumps, another to one hydraulic press, and the third aperture either with a stop or reversing tap, or with a waste pipe. One or the other of the two latter apertures are opened or closed by two valves placed upon one spindle, the top of which has a screw working in a nut, which screw with the spindle and valves are turned by a handle, the position of the valves being so arranged that when one aperture is open the other is closed; by simply turning the handle the aperture from the pumps can be opened to the press until the desired amount of pressure is obtained, after which the handle is turned so as to close the first aperture and open the other, which communicates with the aforesaid similar stop, or reversing tap or waste pipe, and so on for the entire series of presses, one of the apertures of the last tap being connected with the waste-water pipe. *Patent abandoned.*

2835. A. BARCLAY. "Improvements in electric, magnetic, and electro-magnetic telegraph ropes or conductors." Dated Dec. 10, 1858.

Here the component wires of such ropes or cables are twisted after the fashion of a common rope. The wires may be separated from each other by mechanically separative matter only, or by an insulating medium, or by both. *Patent abandoned.*

2836. A. BARCLAY. "Improvements in obtaining motive power by means of electricity, magnetism, and electro-magnetism." Dated Dec. 10, 1858.

This relates to the obtaining of motive power upon the galvanometrical principle. Any form of galvanometer may be used, and one or more bars or magnets may be used to work on the same centre of motion. The needle bar or apparatus of this galvanometer is surrounded by one or a series of stationary galvanometrical coils, between which and the galvanometer needle or bar there are disposed suitable make and break contact apparatus to put the poles of the galvanometer into and out of electrical or magnetical contact with the source of electrical or magnetical power passing through the galvanometrical coils. With this apparatus a continuous and effective rotary action may be secured. The machinery is preferred to be all secured in a suitable chamber from which the air may or not be exhausted. It is also intended to place rotatory electrical or magnetical apparatus in the interior of an enclosed chamber for the purpose described, the air being exhausted or not. *Patent completed.*

2837. C. HODGSON. "Improvements in the manufacture of fuel from peat, and in apparatus employed therein, part of which is also applicable to the moulding of bricks, tiles, and other plastic materials." Dated Dec. 10, 1858.

This consists in means of cutting peat from bogs, in converting it into pulp by tearing machines, drying it on steam-heated tables, and finally forming it into solid lumps by means of a ram working tightly in a tube into which the peat is fed. The moulding part of the invention is applicable to bricks and other like articles. *Patent completed.*

2838. W. BEARDMORE. "Improvements in steam boilers." Dated Dec. 10, 1858.

Here the steam passing from the steam chests of boilers is passed by the patentee through tubes situated in the uptake or flue leading to the chimney or funnel, and thereby becomes superheated before being supplied to the engines. *Patent completed.*

2839. G. F. WILSON. "Improvements in the manufacture of lubricating oils." Dated Dec. 10, 1858.

This consists, 1, in combining rosin oil with oil produced from bituminous or schistose bodies, such as petroleum, bog-head, or other coal or shale, and by preference the rosin oil used is prepared by distilling rosin by surcharged steam, then producing the rosin oil in the ordinary manner, and then distilling such oil by the use of surcharged steam, and by such means body is given to the oils distilled from bituminous or schistose bodies. 2. In the use of rosin oil with cocoa-nut oil or the oleine of cocoa oil, or the oil or oleine obtained from Calhoun palm, or from the oil or oleine obtained from the kernel of the nut from which palm oil is obtained, by which means oils of suitable body for lubrications are obtained. 3. In combining with the compound oil first described one or more of the oils or oleine's secondly mentioned. *Patent completed.*

2840. G. W. B. KIALLMARK and W. T. TIMEWELL. "Improvements in the manufacture of cements." Dated Dec. 10, 1858.

This consists in placing in the kiln, together with the fuel and cement stone, or other materials from which the cement is made, animal matter, such as horse's hoofs, horn, or other similar substances, which being burnt with the cement, stones, &c., improves

the colour and quality of the cement. *Patent completed.*

2841. W. F. HALL and T. DUTTON. "Certain improvements in fancy buttons for ladies' and gentlemen's wear." Dated Dec. 10, 1858.

This consists in perforating the front or face shell, the edge of the perforation being of a Vandyke or serrated form, the points of which being bent or pointed outward will puncture the fabric with which the front of the button is intended to be covered, and these sharp points so far project through the fabric, and are made to clip and hold a centre ornament. *Patent abandoned.*

2842. J. B. GUTHRIE. "Improvements in the manufacture of india-rubber overshoes." Dated Dec. 10, 1858.

This consists in the application at certain parts of gores, gussets, or pieces of elastic india-rubber, or india-rubber webbing or fabric, into semi-elastic overshoes. *Patent completed.*

2843. S. DUDGSON. "An improved gas-regulator." Dated Dec. 11, 1858.

Here the gas is introduced by a supply pipe into one chamber of the regulator, and from this chamber it passes into a second chamber, but the amount of gas passing from one chamber to the other is regulated by a valve which is caused to open or close a passage between the compartments more or less as required. The valve for regulating the passage of the gas between the inlet and the outlet chamber is carried by a disc or cover, having turned-down edges which enter a trap containing quicksilver or other fluid. One arrangement for operating the disc or cover with the valve attached is to suspend it upon centres or axes placed near one of its ends. The points of these centres or axes rest against bosses or pads in which the points of the centres or axes work, thereby preventing undue pressure on the cover, which, if screwed too air-tight, breaks the joints and causes an escape of gas. There are modifications included. *Patent completed.*

2844. J. HINKS. "Improvements in ships' and other lamps." Dated Dec. 11, 1858.

The inventor makes the chimney of a slightly tapering tubular form, and at its summit places a chamber the figure of which somewhat resembles two very obtuse cones placed base to base. The chimney opens into the chamber, the upper end of the chimney being expanded so as to have the figure of a trumpet-mouth, and nearly corresponding in shape to the lower half of the chamber into which it opens. In the upper part of the chamber a horizontal diaphragm perforated with holes is placed. The lower side of the chamber into which the chimney opens is also perforated to permit the escape of heated air from the lamp. By this construction the burning of the lamp is unaffected by strong winds blowing upon it, or water dashed upon it. It also consists in making the reflectors of ships' lamps and lamps enclosed in cases, of a series of planes arranged round the flame, so as to be perpendicular, or nearly so, to radii drawn from the lamp. *Patent abandoned.*

2845. P. ROBERTSON. "Improvements in shuttles." (A communication.) Dated Dec. 11, 1858.

This consists in manufacturing shuttles by combining with wood, bone, ivory, or metal the hard material formed from india-rubber; and also in manufacturing shuttles entirely of such material. *Patent abandoned.*

2846. C. J. RICHARDSON. "Improvements in apparatus to be applied to chimneys or flues of buildings, for economising heat and reducing the quantity of smoke passing into the atmosphere." Dated Dec. 11, 1858.

Here branch iron tubes are so arranged in the upper rooms of a building that the heated products of combustion from fires at lower parts of the building may be made to heat the air of such upper rooms, and also, if desired, to heat water in cisterns placed in such upper rooms. *Patent abandoned.*

2847. M. SCHAFFNER. "Improvements in smelting zinc ores, and in furnaces employed for this purpose." Dated Dec. 11, 1858.

Here the calumina or other zinc ore is placed in a chamber or muffle around which a flue from a furnace passes. The top of this chamber is formed with hollow bricks, and the bottom with fire-blocks or tiles which rest on masonry at the two sides, and are also supported between the sides with perforated supports. The blocks or tiles at the bottom of the chamber form the top of a flue from a furnace, and the products of combustion from the furnace enter this flue at one end of the chamber, and pass on beneath the chamber to its other end where the flue rises up, and the products of combustion then pass back above the chamber through the hollows in the bricks forming its top to a chimney, by which means the chamber is sufficiently heated to volatilize the

zinc. At one side of the chamber there are holes through which the zinc ore is introduced into the chamber. These holes are closed air tight when the furnace is in operation. From the chamber or muffle pipes descend to a condenser in which the zinc is deposited in a liquid state, and can be run off when desired through a small tap-hole. From this condenser pipes pass to another condenser which arrests the metal which passes away with the gases in the state of dust. From the second condenser a pipe in which there is a valve passes to the chimney, so that by opening or closing this valve the gases may be drawn more or less quickly from the chamber. Registers are applied for closing the pipes at certain periods of the operation. *Patent completed.*

2848. W. E. WILEY. "Improvements in over-pointed pencils." Dated Dec. 11, 1858.

The holder is attached to the forcer by a swivel so that the holder and marking material may remain without turning in the case, whilst the forcer is rotated to propel the outer end of the marking material up to and through the nozzle of the pencil case. The forcer is caused to rotate within the case by a split tube which is attached to the end of the case. The teeth or projections of the forcer pass through the split tube and enter the threads of the female screw formed on the interior of the case. It is preferred that the nozzle should be fixed to the case, and that the split tube should be fixed to the other or moveable end of the case. A length of marking material is supplied to the holder when the holder and the split tube has been drawn out of the case. *Patent completed.*

2849. A. ROLLASON. "Improvements in the manufacture of waterproof tissues, and in applying such waterproof material to woven fabrics, and manufactured fibrous goods." Dated Dec. 11, 1858.

This consists, 1, in the preparation of a waterproof tissue, which is capable of application as a remedial agent in surgical cases. 2. In the application of this tissue to the coating of woven fabrics and fibrous or textile goods. To make the tissue the patentee mixes collodion vegetable oil (by preference castor oil) and sometimes Canada balsam, mineral naphtha, and spirits may also sometimes be added. The mixture is poured upon glass plates, and the spirit is evaporated from it, after which the tissue may be stripped off the plates and stored away for use. *Patent completed.*

2850. J. A. CARRUTHERS and T. BLACKBURN. "Improvements in apparatus for guiding and regulating the warp threads in the operations of warping, tape sizing, looming, and weaving." Dated Dec. 13, 1858.

This consists in substituting for the ordinary comb or wraith used in warping and sizing machines a compound spiral spring in connection with a longitudinal shaft or rod, at the extremities of which are placed right and left hand screws with the necessary nuts or apparatus for working the same, so that by turning handles, levers, or wheels, the inventors are enabled to expand or contract the threads or divisions of the springs equally to any desired pitch, by which a greater or less number of ends or threads of the warp may be placed upon any given width. They also place between the divisions of the compound spiral springs peculiar forms of straight springs, either in separate parts or in one entire piece constituting the desired length of the comb. *Patent completed.*

2851. R. WHITTAM. "Improvements in machinery or apparatus for tracing designs from an engraved roller or from an engraver's sketch upon steel or other metallic surfaces, used as dies by engravers to calico printers." Dated Dec. 13, 1858.

This invention is not described apart from the drawings. *Patent completed.*

2852. L. C. V. YOX. "Improved elastic beds." Dated Dec. 13, 1858.

The object here is to facilitate the package of spring mattresses by a mode of construction which permits of their being folded either in length or in breadth. The mattresses are divided into different parts, which assume a square, oblong, or other shape, and which are tied together with gutta-percha bands. To give the intended shape, the inventor makes use of hinge springs, and maintains the opening in breadth by rattans. *Patent abandoned.*

2853. J. M. ROTHSSEL. "A new system and new apparatus, using air as a motive power." Dated Dec. 13, 1858.

This essentially consists in the use of compressed air. The invention is not described in detail apart from the drawings. *Patent abandoned.*

2854. J. E. BOYD. "Improvements in candlesticks, lamps, and lanterns." Dated Dec. 13, 1858.

This invention is not described apart from the drawings. *Patent completed.*

2855. R. A. BROOMAN. "Improvements in twisting and otherwise operating upon threads, twine, or cords, and in apparatus for performing the same." (A communication.) Dated Dec. 13, 1858.

The object here is to perform by machinery certain operations which have hitherto been performed by hand. The invention is not fully described apart from the drawings. *Patent completed.*

2856. R. A. BROOMAN. "Improvements in the manufacture of cranked axles and shafts." (A communication.) Dated Dec. 13, 1858.

This relates to a previous patent, and consists in means of forming the cranks with or without the welding on of additional metal to the bar which is to form the cranked axle or shaft. *Patent completed.*

2857. E. LOOMES. "An improvement in the construction of steam-engines." Dated Dec. 13, 1858.

Here the object is to get the benefit of the reactionary power of high pressure steam supplied to reciprocating steam-engines by causing the steam to enter the cylinders through a moving instead of through a fixed body. To this end the inventor uses a hollow piston rod, which he brings into communication (either through a telescopic arrangement of tubes or otherwise) with the steam supply pipe, and he also makes the piston hollow, and furnishes it with steam ways opening out to opposite sides of the piston. Within the piston he mounts the cut-off valve, the rod of which passes through the centre of the hollow piston rod, and out of the end thereof, which is closed by a stuffing box. By connecting this rod with a crank eccentric or its equivalent worked by the engine, the valve may be readily made to cut off the supply of steam alternately from one end of the cylinder, and open a communication between the supply pipe and the other end of the cylinder. *Patent abandoned.*

2858. J. FERRABEE. "Improvements in the construction of steam-engines, and in the mode of working the same." Dated Dec. 13, 1858.

This relates, 1, to a mode of working the cut-off valves of steam-engines, and consists in the use of an arrangement of parts whereby the supply of steam to the cylinder is cut off at any portion of the stroke of the piston by a continuous motion of a cut-off valve, the time of the cut-off being altered by the rising or falling of the governor balls, and the supply of steam to the cylinder regulated without the intervention of a throttle valve. It relates, 2, to the construction and setting-up of the cylinders of steam engines with the view of maintaining or increasing the elasticity of the steam supplied thereto when discharged from the boiler. *Patent completed.*

2859. J. WEBSTER. "A new or improved method of recovering copper and zinc from liquids, which have been employed to dip or pickle articles made of brass or other alloys containing copper and zinc." Dated Dec. 14, 1858.

This consists in a method of recovering copper and zinc from liquids which have been employed to dip or pickle articles made of brass or other alloys containing copper and zinc by treating the liquids with metallic zinc, and thereby precipitating the copper and zinc contained in the liquids, the same being recovered by evaporation and crystallization. *Patent completed.*

2860. E. BOW. "Improvements in pumps." Dated Dec. 14, 1858.

The essential feature here is the use of a kind of "cup packing," which in the piston acts against the barrel surface in such a way as to dispense with a separate piston packing. *Patent completed.*

2861. D. ANDERSON. "Improvements in taps or valves." Dated Dec. 14, 1858.

Here in a modification of a tap or nose-cock the shell of the tap is made in two parts for the introduction of the closing valve, which is a slightly conical plug of metal, or metal covered with caoutchouc, &c. The plug or valve is fixed on a spindle the inner end of which works in a bridge-piece on the back part of the shell, the outer end passing out at the front of the top to a button or handle by which it is operated. The front part of the shell is made conical internally, the narrow end being outward, and the plug closes this space by the pressure of the fluid, or by the pressure of a spring introduced in cases where the pressure in the pipe is insufficient. The tap is opened by pressing in the spindle, and with it the plug which allows the fluid to escape round the plug. In a modification of valve for discharging fluids, &c., the duct or passage is closed by means of a valve working across its mouth, which is faced or ground up, as is also the back of the valve to make a close fit. The valve is made to slide (by preference vertically) in grooves or guides which retain it against the mouth of the duct or passage,

and it is moved by a handle fixed to it and projecting in front. There are other arrangements included. *Patent abandoned.*

2862. J. WADE. "Improvements in means or apparatus employed in weaving." Dated Dec. 14, 1858.

The object here is the obtaining facility in changing from plain weaving to twill, &c., and then to plain again. Instead of employing only a pair of treddle levers operated by a pair of tappets to give motion to the heddles, there are four or more treddle levers connected to the heddles, according to the extent of change which it may be desired to produce with a separate tappet or like-acting surface to each treddle lever adapted to produce the required variation in the shedding. And these treddle levers are capable of being connected together so as to form one pair, and then ordinary plain weaving will be produced. Catches operate to connect the two or more levers together, and these connecting means are separated at the times desired by Jacquard or other pattern surface. *Patent completed.*

2863. G. BAKER. "An improved construction of manger fastening." Dated Dec. 14, 1858.

The object here is to secure horses and cattle to their mangers, so that on an alarm of fire being given all the animals occupying a long shed or range of stables may be quickly released without the necessity of entering the several stalls to disengage the animals. To this end the patentee provides a peculiar construction of bolt fastening. *Patent completed.*

2864. R. A. BROOMAN. "An improvement in transmitting electric telegraph signals." (A communication.) Dated Dec. 14, 1858.

This relates to transmitting electric telegraph signals by means of clockwork, and consists in setting free the clockwork and bringing it into action, and stopping it by the current itself. *Patent completed.*

2865. J. T. SMETS. "A method of making vinegar from a refuse product obtained in the manufacture of starch." Dated Dec. 14, 1858.

This consists in a process, which we cannot give in detail, of making vinegar from the residuum which remains in the manufacture of starch, and which is generally used for feeding cattle. *Patent abandoned.*

2866. F. JOSSA. "Improvements in furnaces for generating steam and other purposes." Dated Dec. 14, 1858.

This consists in so constructing furnaces that the fire burns downwards, and thus consumes the smoke. *Patent completed.*

2867. J. PENDLEBURY. "Certain improvements in machinery or apparatus for bleaching or cleansing textile fabrics or materials." Dated Dec. 15, 1858.

This consists in an arrangement of vessels for bleaching or cleansing manufactured or piece goods or yarns of cotton, linen, or other fibrous material by the application of high pressure steam for first boiling the bleaching liquid above 212° in a separate closed vessel, and then forcing such liquid so heated through the goods or fabrics to be bleached, the goods being contained in a closed vessel or "kier" conveniently situated near to the heating or boiling vessel. The liquid after being thus forced in a heated or boiling state through the goods, is returned to the boiling vessel, where it is again heated to the required temperature, and again forced through the goods, such process being repeated until the goods are sufficiently bleached. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated May 27, 1859.

1310. L. D. JACKSON. An improved machine for cutting wood.

Dated June 22, 1859.

1498. W. BUCKWELL. Manufacturing materials for building and other structural purposes, and of the machinery applied thereto, which last invention is applicable to other purposes.

Dated June 23, 1859.

1510. A. J. DESSALES. An improvement in the working and securing of sliding tubes, applicable to gas chandeliers, lamps, and other purposes.

Dated June 30, 1859.

1554. A. GUYTON. Improvements in enamelling articles of jewellery, applicable also to other similar purposes.

Dated July 5, 1859.

1598. J. H. NALDER and T. NALDER. Improvements in winnowing and dressing grain and seeds, and in the machinery or apparatus employed therein.

Dated July 6, 1859.

1600. W. H. WARD. Ocean marine signal telegraphing for day and night, whereby messages and communications on all occasions and subjects may be given with clearness and despatch, within seeing distance, day or night.

1606. B. SEED and T. STEEL. Improvements in apparatus employed in the treatment of soap suds or other saponaceous or oily matters.

Dated July 7, 1859.

1610. D. T. JONES. Improvements in ploughs.

1611. C. F. VASSEROT. An improved form of regulator, chiefly applicable to water-wheels. A communication.

1612. F. A. LE MAT. Improvements applicable to ordnance.

1614. R. C. RAPIER. Improvements in working rolls for rolling plates of unequal thicknesses.

1618. J. H. JOHNSON. Improvements in knitting frames. A communication.

Dated July 8, 1859.

1619. G. ELLIS. The improvement of muffs, to be called "the patent reticulate travelling muff."

1620. W. H. DAWES. An improvement or improvements in the manufacture of iron.

1622. F. A. LE MAT. Improvements in the construction of revolving or repeating fire-arms.

1624. G. CARTWRIGHT. Improvements in corks for bottles and jars.

1625. G. A. BOGGIS. Improvements in rendering boots and shoes waterproof.

1626. E. LIVERMORE. Improvements in the manufacture of burning fluids for illuminating and heating purposes. A communication.

1627. D. MATHEWS. Improvements in apparatus for refrigerating and heating liquids.

1628. J. H. JOHNSON. Improvements in moulding or shaping metals by pressure, and in the machinery or apparatus employed therein. A communication.

1629. W. H. HARFIELD. Improvements in ships' capstans, and riding bits.

1630. H. BRIMSMEAD and J. LAWRENCE. Improvements in rotatory screens.

1631. J. TAYLOR. Improvements in the construction of walls to prevent damp from rising, and also in tiles to be used for this purpose in building walls.

1632. T. D. DUPPA. Improvements in carpenters' benches.

1633. W. WOOLF. Improvements in ploughs.

1635. W. N. NICHOLSON. Improvements in clod crushers and land and garden rollers.

Dated July 9, 1859.

1636. M. HENRY. Improvements in the manufacture of over-shoes and other articles worn on the feet, and in the apparatus employed therein. A communication.

1637. B. SAMUELSON and J. SHAW. Improvements in reaping and mowing machines.

1638. E. AYCKBOURN. Constructing certain articles of dress, so as to prevent drowning.

1639. C. ILIFFE. Improvements in the manufacture of buttons.

1641. E. LIVERMORE. Improvements in generating gas for the purpose of lighting and heating.

1642. J. SMITH. Improvements in apparatus for heating and cooling water.

Dated July 11, 1859.

1643. E. F. HUTCHINS. Constructing the jaw or jaws of vices and holding tools in general with a ball and socket joint.

1644. R. CLEGG. Improvements in machines for cutting wood and metal, and in the means of fixing saws thereto. A communication.

1645. H. DAVIS. Improvements in the manufacture of soap.

1646. J. C. PICKARD. Improvements in web forks for looms.

1647. W. E. NEWTON. Improvements in magneto-electric machines. A communication.

1648. J. DIBLO and W. H. GRAVELEY. Improvements in apparatuses for ventilating and lighting ships.

1649. F. BURDEN. Improvements in the permanent way of railways.

1650. J. A. HARTMANN. Improvements in the manufacture of colours for printing cotton and other vegetable fibres and silk.

PATENT APPLIED FOR WITH COMPLETE SPECIFICATION.

1690. W. M. CRANSTON. Improved delivery apparatus for harvest machines. A communication. Dated July 16, 1859.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

(From the London Gazette, July 26, 1859.)

637. J. Court. Nibs for gas burners.
 638. R. Allison. Boring and sinking.
 657. W. Robertson and J. G. Orchar. Weaving.
 660. I. Ash. Locks and latches.
 668. J. Clark. India-rubber fabrics.
 669. G. Hamilton and W. H. Nash. Locks and keys.
 671. T. W. Miller. Blocking ships.
 672. C. Defries. Lamps.
 678. A. G. Hutchinson. Counteracting damp.
 679. P. Laroche. Brewing.
 690. R. Mushet. Metallic alloy.
 691. R. Mushet. Cast steel.
 692. A. L. Thirion. Mills.
 696. W. B. Gingell. Window sashes, &c.
 703. R. Mushet. Cast steel.
 708. A. Bauco. Graters.
 712. J. Roberts. Packings for pistons.
 717. W. Rhodes. Fire-proof safes.
 719. J. Davies. Musical instruments.
 721. W. A. Gilbee. Silk thread. A communication.
 722. W. Weild. Coating slips, bars, laths, &c.
 727. D. L. Banks. Suspension ways.
 730. T. Manlove and W. Hodgkinson. Textile fabrics.
 732. J. Tyssen. Indicating the speed of ships.
 741. J. V. Hielakker. Pressing or moulding.
 752. C. Sanderson. Steel.
 778. T. Carr. Disintegrating substances.
 790. W. Brown. Clog-soles.
 800. A. V. Newton. Governor. A communication.
 818. W. E. Newton. Cricket bats. A communication.
 993. J. Wotton. Shaping metals.
 1222. L. D. Owen. Truss. A communication.
 1268. C. P. Moody. Matting.
 1270. F. J. Bramwell. Raising ships. Partly a communication.
 1410. F. Puls. Hydro-carbons.
 1542. J. Nash. Disengaging block.
 1544. A. McDougall. Disinfecting substances.
 1552. G. Baker. Trellis work. A communication.
 1590. R. A. Brooman. Hemmer for sewing machines. A communication.
 1593. J. H. Nalder and T. Nalder. Dressing grain.
 1599. J. Watkins and J. Pugh. Lubricating wheels.
 1613. J. Knowelden and D. Edwards. Hydraulic engines.
 1627. D. Mathews. Refrigerating and heating.
 1637. B. Samuelson and J. Shaw. Reaping and mowing.
 1639. C. Iliffe. Buttons.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed July 22, 1859.

202. B. Templar.
 203. E. Dorsett and J. B. Blithe.
 212. R. A. Brooman.
 213. J. Laubercou.
 214. J. Smith and W. H. Smith.
 215. J. Savory and W. R. Barker.
 217. A. Warner and W. Tooth.
 227. J. White.
 238. D. Graham.
 240. F. C. C. Paulsen and A. Aiding.
 270. W. E. Newton.
 355. T. Willis and G. Chell.
 617. A. V. Newton.
 833. T. Richardson and G. W. Jaffrey.
 851. L. Brierley and H. Geering.
 1263. W. Crum.

Sealed July 26, 1859.

246. E. Dixon and H. Whittaker.
 253. W. Crowther.
 254. J. Gathercole.
 255. I. Zacheroni.
 259. F. Prince.
 266. J. MacKenzie.
 270. J. A. de Brona and A. J. M. Icherrypoon.
 272. T. P. Smith.
 274. J. Raywood.
 280. R. A. Brooman.
 297. E. Wilkins.
 307. T. Storer.
 330. W. Clark.
 342. M. Curtis & J. Miller.
 343. J. Lee.
 359. T. S. Cressey.
 373. H. P. Burt.

NOTE.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office.

LIST OF DESIGNS FOR ARTICLES OF UTILITY REGISTERED.

Dates of Registration.	No. in Register.	Names and Addresses.	Subjects of Design.
June 24,	4184	J. Cornes, Barbridge Works, Nantwich	Cheese making apparatus.
" 27,	4185	H. Naylor, Sheffield	Engravers' assistance.
" 29,	4186	J. W. Scott, Worcester	Stud-button shank.
July 1,	4187	C. H. Thew, Whitehaven	Draw-spring for ships' cables.
" 4,	4188	J. W. Mott, Lead Bridge Road	India-rubber tobacco pouch.
" 7,	4189	J. Adams, King William Street	Tool for filling cartridges &c.
" 18,	4190	J. Chesterton, Leicester	Appendage to fire-arms.

PROVISIONAL REGISTRATIONS.

June 30,	1063	W. Press, Walburgh St.	Quick action drill-stock.
July 1,	1064	G. Kings, Tyburn, near Birmingham	Self-acting break.
" 9,	1065	J. Chandler, Creek Foundry, Deptford	Glass water-gauge.
" 12,	1066	T. E. Ladd, Walcot Place East, Walworth	Watch protector.
" 14,	1067	J. Major, New Street Hill, Shoe Lane, E.C.	Economic gas-burner.
" 16,	1068	C. Price, Mill Street, Wolverhampton	Lock.
" 18,	1069	Brown & Clark, Richard Street, Birmingham	Cigar-holder.

LIST OF MISCELLANEOUS TENDERS INVITED, AND ENGAGEMENTS OPEN.

The tenders and vacancies which appear in this weekly list are not repeated in succeeding numbers.

WIDENING RIVER, *Beckingham, Fenton, &c.*—For building new bridges and sluices, and repairing existing bridges, forming flood-banks, &c. Plans, &c., office of Mr. C. J. Neale, Mansfield. Tenders to August 11.

CHURCH, *East Markham, near Tuxford, Notts.*—Restoring and refitting. Drawings, &c., Rev. G. W. Bramet, Vicarage, East Markham. Tenders to August 1st.

CORN MILL, *Leeds.*—For the engineers, millwrights, builders, joiners, and other workmen of a corn mill to be erected in Tenter-lane, Leeds. Apply to Messrs. Bevers and Wightman, Leeds.

POOR-LAW OFFICES, *Leeds.*—For the excavators', masons' work, bricklayers' work, carpenters and joiners' work, slaters' work, plumbers and glaziers' work, plasterers' work, iron-founders' work, and painters' work, requisite for building the new Poor Law Offices in East and South Parade. Plans, &c., and form of tender, on application to the Architect, 71 Albion-street, Leeds. Tenders to 12 o'clock, August 3.

POLICE STATION, *Crediton.*—For the erection of a Police Station and Petty Sessions room at Crediton. Plans, &c., at the office of Mr. Henry Ford, Clerk of the Peace, Castle of Exeter. Tenders to August 3.

SEWERING, PAVING, &c., *Manchester.*—For the sewerage paving, &c., of Carter-street, from Julia-street to Carnarvon-street, New-street, from Julia-street to Frances-street, Melbourne-street (Julia-street). Plans and specifications, and blank forms of tender, on application to Mr. William Frances, the Surveyor, at the Town Hall. Tenders to August 26.

WORKHOUSE, *Scotland.*—For the erection of Galashiels Union Poor-House, at Galashiels. Plans, &c., Mr. Stalker, Writer, Galashiels; or of Mr. Walker, Architect, 55 Frederick-street, Edinburgh. Estimates for the

whole, or portion; but the amount of each trade must be stated separately. Tenders Mr. Walker's office August 3.

FARM HOUSE AND BUILDINGS, *Newend.*—On the Old Clifford estate. Plans, &c., Mr. Washbourn, Solicitor, 12 Palace Yard, Gloucester, to August 5; where sealed tenders addressed to the Clerk and Solicitor of the Trustees of St. Kynburgh, otherwise St. Kimbros Hospital, Gloucester. Further particulars, Mr. J. C. Jackson, Surveyor, Gloucester. Tenders to the Chief Clerk of the Vice-Chancellor of the Court of Chancery.

QUAY WORK, *Scotland.*—To form a new margin for the river Clyde to stop further encroachment by water, and to form a new embankment to prevent the Holm Lands from being flooded. All on the farm of Mid Holm of Grange, in the parish of Pellthain. Plans, &c., Mr. R. Denholm, Factor, Carmichael, by Lanark; and Mr. Stodart, Hill Head, Covington. Estimates with Mr. Denholm, August 2.

SEWER, *Lambeth.*—For laying down, constructing, &c., 2,550 feet or thereabouts of brick sewer, in Paradise-road, Binfield-road, and Charlotte-street; and for the maintenance thereof in complete repair for 12 calendar months. Plans, &c., Mr. Hugh Macintosh, Surveyor of Sewers, Office of the Vestry, Kemington Green; to which place tenders before 4 o'clock on the afternoon of August 1.

SEWERS WORK, *St. Leonard's, Shoreditch.*—For the supply of materials, and the execution of the day, jobbing, and measured works, for the sewers, drains, gullies, &c., in the parish, under the control of the Vestry from the 2nd day of August next, for a period to be determined. Forms and specifications 5s. each, with information, Mr. W. Y. Freebody, Chief Surveyor to the Vestry, 37 Hoxton-square, where tenders before 5, August 2.

SOUTH WALES COAL, *Navy.*—For Trincomalee, 2,500 tons, Bermuda 2,000, Jamaica 5,000, Barbadoes 600, and Halifax 500 tons. Tenders at Somerset Place by two o'clock, August 2, containing the names of two sureties in £1,600 for Trincomalee, £700 for Bermuda, £1,500 for Jamaica, and the name of one surety each in £200 for Barbadoes and Halifax. The attendance of a principal or agent indispensable. Particulars and form at Somerset Place.

TWISTED IRON SPIKES, *East India Railway.*—For 400 tons as per specification at the offices of the Company. Tenders, August 2, D. I. Road, Secretary East India Railway House, Alderman's Walk.

PLANS AND ESTIMATES FOR NATIONAL SCHOOLS, *Sutton, near Ely.*—The school to be in the form of the letter L, and to comprise two rooms of equal dimensions, 40 feet long by 20 feet broad. Also a master's house attached. The whole, with the internal fittings of the school-rooms, to be in strict conformity with the paper of instructions to architects and builders furnished by the Committee of Council on Education. Application to see the site and paper of instructions, to Mr. Tubbs, Sutton; to whom plans and estimates, for the Committee, up to August 6. Any further information from the Secretary, Everard Calthorpe, Esq., Sutton.

RAILWAY SERVANTS.—Station-masters, engine-drivers, stokers and guards, for the Cork and Youghal Railway. Applications in writing from experienced and qualified persons to be sent, accompanied by testimonials, by August 1, to O. C. Edwards, Esq., Engineer to the Company, St. Patrick's Hill, Cork. No personal application attended to. Offices of the Company, 176 Graham House, Old Broad-street, London.

REMARKS.—Our Metal Market has been quiet during the week. Prices nearly unaltered.

LAWRIE AND HAGGER, Metal Brokers.

33 Lombard-street, E.C.

education and authorship has a claim upon our confidence. We allude, of course, to Mr. Chatfield, who not only refuses to sign the Report of his colleagues, but puts forth very cogent reasons for dissenting from almost every important conclusion they have come to. They think the "morning meetings" of the principal officers have become mere forms; Mr. Chatfield says they have not. They think the smitheries should be under the control of the Chief Engineer; he thinks quite the contrary. They say the *Cossack* was a cheap vessel; he says £9,368, were expended in four years upon her after her so-called completion. They recommend "day pay" with "proper supervision" instead of the "task and job" and other systems; he considers that to talk of "proper supervision" is to beg the question. They think the system of shipbuilding pursued in private yards should be imitated in the Royal Dockyards; he says, "so far from imitating the system of private yards, we should take great care to avoid it." They deem the resort to varieties of day pay advisable; he deems it "very unadvised to attempt to reintroduce a system which has been tried and failed." They advise the substitution of deferred annuities for the workmen's present superannuation; he wholly disapproves of such a change. They urge the return to leading men and quartermen; he "strongly advises not returning to a system inferior," in his opinion, "to the present." They also urge the removal of inspectors, and a consequent decrease in the amount of supervision exercised over the workmen; he states "it would not be advisable to reduce the amount of supervision," which he considers "to be already at its minimum." They suggest certain changes in the position of draughtsmen; he calls their proposals suggestions, the object of which he "cannot understand." They propose a reduction in the salaries of foremen; he "should not recommend it." They would adopt a modification of the timber inspectors' position; he deems their plan "the reverse of any change that might be considered expedient." Finally, they desire to introduce a peculiar class of superior pupils; he says, "if the plan proposed 'by the majority of the Committee were adopted . . . my conviction is, that such a 'step would prove a total failure.' We cannot compliment Mr. Chatfield upon the course he has taken in this matter, because as a sensible and educated shipbuilding officer, free from malevolence and party feeling, he could not for a moment have thought of committing himself to the vagaries of his associates. We may, however, and hereby do, tender him our thanks for taking the trouble to convict them of much absurdity. His withdrawal leaves us a Committee of four only.

We shall do no violence, we presume, to any one's sense of right if we next remove from this reduced Committee their gallant chairman, Admiral Smart. We need say but exceedingly little in defence of his removal; for he must be an exceedingly smart Admiral indeed who, from a little superficial acquaintance with establishments like our Dockyards, could derive the right to have a voice even in the subversion or transformation of those huge manufacturing establishments.

Thus our Committee has dwindled down to three. May we let the trio remain? Tell us, Mr. Bowman, may we? Alas! poor man, we believe he cannot answer, Yes! We know Mr. Murray and we know Mr. Laws; and we greatly fear from Mr. Bowman's autobiography (published in the *MECHANICS' MAGAZINE* for June 24, pp. 410—411) that he is not the man to set up an opinion of his own, if he should happen to have one, against two such opponents,

however much he might desire to do so. We shall be pardoned, we hope, if we venture to glance a moment at the position of this Mr. Bowman. In an article published towards the end of April last we happened to mention this gentleman as "one of Mr. Lindsay's foremen." This hurt the pride of our Admiralty Committee-man, and he hastened to protest against the imputation. In doing this he incidentally told us both what he is and what he has been. This is what he says of himself:—In 1824 he obtained a patent for a chain cable stopper; he was then manager of Messrs. Simson and Co.'s engine works at Aberdeen. In 1838 he started a firm, Bowman, Vernon, and Co., "engineers and iron shipbuilders." He next "left that firm and went into Staffordshire"—the "firm" turning out a bad speculation, we presume. In July and August, 1847, he contributed some remarks on cast iron to the *MECHANICS' MAGAZINE*. He next "joined the firm" of G. B. Thorneycroft and Co. as "superintending engineer," and on June 8th, 1850, Mr. Thorneycroft mentioned him favourably in the *Mining Journal*. Finally, in 1853, he "left that firm," and commenced his practice of consulting engineer. This wandering gentleman, who has made his way into so many "firms" and stopped in so few, and who, even when he was the head of his own firm, did not give satisfaction apparently—this gentleman modestly tells us that he should not wish that either our mind or that of the public "should have the impression that one of the 'members of the late Dockyard Committee 'was only a foreman of Mr. Lindsay's.' And yet in the very same letter he tells us that "he did superintend the construction of five steamships for Mr. Lindsay," and adds that he no doubt owes his appointment on that committee "principally to that gentleman." So that this high-mettled Committee-man, who would object to being employed as a foreman by Mr. Lindsay, thinks it no disgrace to be patronized and pushed into office by him! The character of this person must be borne in mind hereafter, for as we shall show in future articles, his three colleagues and he have the effrontery to tell us how *gentlemen* should be trained for high positions, and to warn us against giving too many opportunities of rising in the world to the sons of working men.

We have thus seen that Mr. Chatfield is too sensible, that Admiral Smart is too uninformed, and that Mr. Bowman is too puerile, to be held responsible for this Report. The Committee is, therefore, reduced to two members. Of these Mr. Laws is a storekeeper, and before he became storekeeper was a clerk. It can hardly be expected, therefore, that he would be very dogmatical in deciding the purely professional questions of the shipwright and the engineer; more particularly as certain crochets in connection with the keeping of accounts form his peculiar hobby. If Mr. Murray would yield to him on these points, he would unquestionably yield to Mr. Murray on others.

Thus, by simply opening our eyes, and looking these Committee-men in the face, so to speak, we have discovered that Mr. Andrew Murray, Chief Engineer of Her Majesty's Dockyard, Portsmouth, is the man, and the only man, who has really put forth (in so far as manufacturing processes are concerned) the striking Report before us. He it is who has undertaken to settle (or rather unsettle) of himself the whole shipbuilding and engineering establishments of the Government Dockyards. Now, that Mr. Murray deems himself fully competent to execute the task which has thus devolved upon him, we do not for a moment doubt. He has before tried to make a little knowledge go a long way, and

there is no reason why he should not do so again. If we are rightly informed, he lately undertook the revision, not to say the composition, of a treatise on naval architecture; his plea probably being that he studied shipbuilding under Mr. Fairbairn! He is not, therefore, a man to shrink from large undertakings from any excessive sense of modesty. There is, however, one consideration which, one would have thought, might have weighed with him, viz., that Sir Baldwin Walker, whose management of the navy is deeply involved in the Report before us, is both a gentleman and Mr. Murray's superior officer. We do not for a moment say this should have made him in the slightest degree unfaithful to his convictions (although it ought, perhaps, to have kept him out of the Committee altogether), but it should have had a moderating effect upon his prejudices, and kept his proposals within bounds. But we waste words on this point if it be true, as some think, that Mr. Murray is not only a warm partizan of the late Admiralty, but a special instrument in the hands of Mr. Corry, the late Secretary to the Admiralty. If this be so, we need not be surprised at even the extremes of folly which are embodied in this Report. There is, however, another consideration which, although it has not occurred to Mr. Murray, has struck many persons, and that is, the absence of all grounds for public confidence in his opinions. What has Mr. Murray ever done to gain the respect, or even the attention, of public men? Will any reader tell us? As he has not scrupled to deliver himself of opinions upon shipbuilding matters wholly adverse to the master shipwright associated with him, we have a right to ask what he knows of the shipwrights' trade, or of the naval architects' profession. Has he ever built a ship? Has he ever designed one? If he has, did she float upright? And if she did, how much "brick" ballast was necessary to keep her so? There are old acquaintances of Mr. Murray who would like to see these questions answered. But, to say no more of the shipbuilder's business, what has Mr. Murray done to distinguish himself as an engineer even? He has gained a good position at Portsmouth, it is true, but that is no proof of professional eminence. When he got that appointment, partizanship was more regarded than ability, and at that time many a man who was never suspected of being skilful in his profession climbed high. His promotion of itself, therefore, affords no mark of ability. Where, then, are his proofs of eminence? Many an echo will, we are confident, answer "Where?"

The utter unfitness of this Committee for its work, and the foolishness which prompted its appointment, are abundantly evinced in the result of its deliberations. Its sittings have been prolonged for a year, and the expense occasioned by it will be reckoned by thousands of pounds sterling. And what is the fruit of all this? A Report which no Government would dare to act upon, except, perhaps, in some few minor matters. Mr. Chatfield's honourable and necessary dissent has, of course, rendered it utterly worthless, in so far as all the great questions of economy discussed in it are concerned. The present Admiralty—and the late Admiralty also—know as well as we do that it is everywhere esteemed as little more than Mr. Murray's manifesto against the present management of the Dockyards, coupled with a daring and monstrous attempt of his to fling as many as possible of the shipbuilding departments of the navy under the feet of the chief engineers. The Admiralty also know perfectly well that any attempt to give effect in the Dockyards to the devices and desires of Mr. Murray's hearty would arouse so strong a sense of injustice

and excite such wide-spread hostility, that failure would inevitably ensue.

We cannot now enter upon a discussion of the details of this Report. There are many, very many, features of it which we shall have to consider hereafter. All that we can at present add is that we shall, in a future article or articles, adduce from it stronger examples of ignorance and absurdity—not unaccompanied by what we can only call snobbishness—than have ever before astonished our eyes in any official report whatever.

THE DECIMAL SYSTEM OF MEASUREMENT.

At the general meeting of the Institution of Mechanical Engineers held in Birmingham on the 27th ult., Mr. John Fernie, of Derby, a gentleman of distinguished merit as an engineer, read a very encouraging paper on the application of the decimal system of measurement to mechanical engineering work—a paper deserving all the prominence which we can afford it. The subject has been brought forward at previous meetings of the Institution by Mr. Whitworth, who proposed the inch as the standard of length for mechanical engineering work and metal manufacturing purposes generally, the inch being subdivided decimally into 1,000 parts. The application of this system has been already commenced in the locomotive shops of the Midland Railway, at Derby, in which Mr. Fernie labours professionally, and he is satisfied from the experience already gained of its working that its general adoption would be attended with much less real difficulty than might appear at first probable, without involving any objectionable changes. By taking the inch as the standard of length, all difficulty attending the adoption of a new standard is avoided; for many dimensions common in mechanical engineering work are already expressed in inches, and the inch is the unit of measurement in calculations of steam pressure, strength of sections, &c.; while even in larger dimensions, as in bridge girders, &c., no more figures are required in most cases for expressing the dimensions in inches alone than in feet and inches. With respect to the metre, adopted as the standard of length in France, the extreme difficulty of its introduction in this country would amount to an indefinite postponement of the whole question, if it did not render it absolutely impracticable; and the inch has an advantage as a standard in the present case from its decimal subdivision affording a finer division for line measure than is obtained by the decimal subdivision of the metre, and with one place of decimals less. With the metre the smallest dimension of line measure is the millimetre, .001 metre, or one-thousandth of a metre, requiring three places of decimals, and equivalent to about .04 inch; whereas with the inch the smallest dimension of line measure is .01 inch, or one-hundredth of an inch, requiring only two places of decimals, while it is only about one quarter the length of the millimetre. The inch is moreover in effect the present legal standard in this country, the yard or parliamentary standard being fixed at 36 inches, of which the seconds' pendulum is 39.14 nearly.

An important step has been already effected in carrying out the decimal system, by the decimal wire gauge introduced by Mr. Whitworth, in which no alteration is made in the sizes ordinarily used, the names only being changed to one uniform series representing the exact value of each size in thousandths of an inch. Thus in the ordinary or Birmingham wire gauge the No. 20 conveys no idea of the size it is intended to denote, and the same size is represented by a different and unconnected

number in each of the five different gauges now in use, being No. 62 in the Lancashire wire gauge, No. 13 in the metal or plate gauge, No. 18 in the music wire gauge, and No. 3 in the needle wire gauge. But in the new decimal wire gauge all these different numbers are replaced by one No. 36, the actual size being .036 inch, or 36 thousandths of an inch, thus denoting the exact size that it represents.

In order to obtain the degree of accuracy required in an engineering workshop, where the one-thousandth of an inch is distinctly appreciable by the workman in making the fitting parts of machinery, a measuring machine has been constructed by Mr. Fernie, on a similar principle to the delicate measuring machine invented by Mr. Whitworth, in which a screw is advanced very slowly by means of a large wheel having a graduated rim, and the required length is measured by end or contact measurement instead of line measurement. This machine affords the means of supplying exact standards of size for all portions of engines or other machinery, whereby perfect accuracy of fit can be ensured, and the exact amount of clearance or exact degree of tightness required is obtained, while the original standards can be at any time repeated or verified.

We may mention in this connection a very admirable instrument, the invention of Mr. James Cocker, of Liverpool, which was lately submitted to us for inspection. This consisted of a disc with a spiral or eccentric circumference, the successive points of which were, of course, at increasing distances from the centre. At the centre an arm is loosely pinned, and this arm carries a pin, which, as the arm is moved round, gradually approaches to or recedes from the circumference of the disc. By varying the form of that circumference any degree of measuring sensitiveness may be obtained. The instrument which we saw (and which was from two to three inches in diameter) readily detected differences as small as one-thousandth of an inch; it therefore showed very sensible differences in the size of hairs taken from the heads of different persons, or from the crown and beard of the same person.*

For the coarser measurements in the workshop the common rules now in use are replaced by decimal rules, twenty or thirty inches long, jointed for convenience at every ten inches, each inch being divided into tenths, and between each tenth a small dot or short mark is made, representing half a tenth of an inch; the workman is then soon able to subdivide this again by eye, so as to measure to two-hundredths or even one-hundredth of an inch, and one-tenth of an inch upon the rule is divided into hundredths of an inch for reference. These decimal twenty-inch rules have been already adopted by Mr. Whitworth throughout his works, and no difficulty is experienced in the change. In figuring drawings, the only alteration to be made consists in writing all dimensions in inches and decimals alone, which has the advantage of preventing mistakes in reading off or adding up dimensions; writing the figures with two places of decimals, even where the se-

* Since the above was written we have observed, in the Report of the Birmingham meeting (at which we were not present) that this instrument was exhibited on the occasion. It is thus described:—"A decimal measuring instrument was shown by Mr. James Cocker, of Liverpool, for measuring small sizes to one-thousandth of an inch, consisting of a flat graduated disc, the edge of which is formed in a spiral shape, with an abutment placed at a definite distance from the centre of the disc; to obtain any dimension the disc is turned round into the proper position, and the space between the spiral and the abutment gives the dimension required." Another small measuring instrument was also shown by Mr. Alfred Knight, of Birmingham, in which small dimensions are indicated to one-thousandth of an inch by an index upon a graduated dial, the indication being magnified by means of a rack and pinion.

cond place is 0, as in the case of 1.50 inch, for the sake of simplicity and accuracy in adding up dimensions; and drawings should be made as far as possible to a decimal scale, such as one-tenth, or one-fifth of the full size. The principle of the decimal system has been also adopted for weights and measures by the recent introduction of the "cental" of 100 lbs. for weighing corn, flour, &c., in place of the clumsy bushel, the weight of which is different in different localities.

SUBMARINE TELEGRAPH CABLES.

ONE thing we have a perfect right to demand of the gentlemen who next undertake to lay down a long and costly telegraph cable, and that is, a careful testing of the cable itself before it leaves the manufactory. Had this precaution been taken with the whole of the Atlantic cable the bells would not have been rung, the Bible quoted, and gold medals distributed in vain.

Our attention has been specially directed to this matter by the performance of some experiments which we lately witnessed at the works of Messrs. Reid and Co., the telegraph engineers of University-street, London. These gentlemen are not content with simply submerging the cable, nor even with subjecting it while submerged to considerable pressure; but they think it necessary to first exhaust the air from the vessel containing the cable, and then force in water until a pressure of about 200 lbs. per square inch is attained. For this purpose they employ a vessel strong enough to resist the pressure of the atmosphere when exhausted, and also the hydrostatic pressure to which the cable is intended to be subjected. This vessel is made with a cover, to allow of a coil of insulated wire being introduced and inclosed therein. One end of the covered wire is conducted from the interior, through a stuffing box, to the outside of the vessel; the other end of the wire is coated over and well insulated. The vessel containing the wire is then exhausted of air, and a vacuum formed by means of air pumps. The stop cock of the air pumps is then shut, and the passage for water is opened in order to fill the vessel; or a quantity of water may be introduced into the vessel, so as to fill or nearly fill it, before exhausting the air. One end of the wire of a galvanometer is connected with the outer end of the wire which has been brought through the vessel. Pressure is next exerted by pumping water into the vessel, and then, on connecting the two poles of the battery with the galvanometer and the water in the vessel respectively, if the insulation be perfect, no action takes place in regard to the needle of the galvanometer, no complete electric current being formed; but if there is any defect in the coating of the wire, however small it may be, it is indicated by the deflection of the needle of the galvanometer, which shows that a circuit has been formed by the water in the vessel getting in contact with some part of the wire which is being tested. It is recommended by Mr. W. Reid, the patentee of the process, that the exhaustion should be as perfect as possible, and that the pressure to which the coated wire is thus subjected should for submarine telegraphs exceed the pressure which the depth of water in which it is to be submerged can ever offer to such wire. For subterranean and similar electric telegraphs a few pounds on the square inch will suffice; but as excess of pressure over that to which it is likely to be subjected when laid down does not injure the wire, or cost much, while at the same time it more certainly insures detection of defects, or what are likely to become defects, it is

recommended that the pressure even for these should be at least 20 lbs. on the square inch.

The process above described needs but little to recommend it. Properly carried out it is certain to reveal any fault that may occur in the manufacture, and thus guard us against laying down a cable until it is found to be perfect. With the best modes of constructing cables we cannot avoid the risk of some defect or other, and it is surely incumbent upon us to detect such defects as may exist before the repair of them is put beyond our power.

MARINE BOILERS FOR THE ADMIRALTY.

WE have already said* that Mr. Nasmyth and his colleagues of the Admiralty Committee on steam machinery decided contrary to the experience of abler men than themselves when they pronounced an opinion adverse to the merits of the Sheerness steam boiler patented by Admiral Tucker and Mr. Blaxland. These gentlemen—the one the Superintendent and the other the Chief Engineer of one of Her Majesty's Dockyards—observing the grave defects of the tubular boilers of H. M. gunboats and other vessels, did precisely what good and efficient servants of the Crown should have done, viz., suggested a remedy for the evils before their eyes. They invented a boiler without tubes, of cheap construction, and altogether free from the well-known defects of the gunboat boilers. To the merits of their invention we have already borne strong testimony, but the apathy of some and the hostility of others are preventing its adoption. The sapient Committee above referred to, of whose abilities we long since had astounding evidence, dismissed its consideration with a rapid sentence or two "signifying nothing."

Admiral Tucker, however, is an officer of some spirit and patriotism, and refuses to accept their decision without comment. He has accordingly drawn up a paper bravely entitled "Observations on part of a Report by the Committee for investigating the Steam Navy; contradicting its statements, and questioning its fairness;" to which paper we would draw attention. "It appears at page 36 of the report," says the author, "that a boiler, of which I am the patentee, was submitted to the Committee's attention; and had the report of the result of the trial of that boiler, as was but fair, and as had been promised, and given by the preceding Board of Admiralty, been submitted to me before printed, the errors in it, to which I shall hereafter advert, might have been, if not avoided, certainly pointed out. But as that, nothing more than the fair course of proceeding, was not in good faith, nor even in courtesy accorded, I resort to this method of making known, first,—How it happened that the boiler was tried in Sheerness-yard, of which I had been the Superintendent; and, secondly,—What the proceedings and facts of the trials in reality were; and I shall venture to suggest, why the expenditure of so comparatively small a sum as £300 should not deter a Board of Admiralty from irrefutably testing the merits of a boiler which eminent and practical men have considered to be superior to the multi-tubular boiler by a saving of 20 per cent. in first cost, more than 23 per cent. in fuel, a greater production by 30 per cent. of steam, besides being by very far the more durable, and the less liable to repair."

Admiral Tucker next tells us that as Captain Superintendent of a naval yard during the late war, he became painfully aware of the constant breaking down and necessary repairs of our gunboats. Their defects, and the question of

making good their repairs by the appointed time, being constantly before him, caused him great anxiety. His reflections, coupled with those of Mr. Blaxland, gave rise to the patent boiler, which, as the projectors believe, fully answered their expectation; and when the result was made known to the Admiralty, an inspection of the model was directed, and subsequently the application of the invention to a boiler of one of the gunboats, and a trial of the patented boilers in comparison with a multi-tubular boiler to be made in Sheerness-yard. To the trials, which were conducted by Mr. Langley of the Sheerness Steam Ordinary, the Steam Committee allude. But it is against the partiality with which these trials were made—Admiral Tucker being himself at that time abroad—that he has frequently complained to the Admiralty. "As, for instance, that all the leakage of the multi-tubular boiler, and all its priming were registered in favour of that boiler as for steam which it had generated; for, indeed, to produce a fictitious report of the desired evaporation, its fires were so urged as to blow off heated cinders, which without doubt would have set fire to any ship had it been afloat, and was considered so dangerous to the dock-yard as to compel the Superintendent's interference, who ordered the fires to be drawn." Again, notwithstanding that the issue of the comparative merits of the two boilers was,—which could work the longest without the loss of power!—the steaming of the multi-tubular could only be continued for a few hours at its full duty, from the constant choking of its lower tubes, and from its making a deposit of live cinders in the smoke box, causing its destruction during the trial by its own fire.

This mode of proceeding being, as Admiral Tucker says, neither satisfactory nor just, he obtained from the Admiralty an order for a trial of 144 consecutive hours. "The patent boiler worked through the period without one single interruption, while the multi-tubular broke down five times, nor ever collectively steamed through the appointed time." This trial having proved that the patent boiler could steam certainly for 144 consecutive hours, while the multi-tubular fell so far short, it was to be inferred that the invention had at least some merit worthy the attention of the Steam Department of the Admiralty, and the more so, because the patent boiler could be so much more economically constructed, and that the novelty could be applied to the boilers already afloat at a much less expense than repairing them with tubes. "So far as I have heard," says Admiral Tucker, "nothing of the kind has been yet attempted by the Steam Department."

However, on the 28th of June, 1858, he was ordered to put himself in communication with the Steam Committee, that the boiler might be tried: and he next proceeds to show that so far from fairly testing its merits, it was the members of the Steam Committee themselves who prevented a fair trial being made on that occasion. Early in the month of June, 1858, (and not the last day in August, the day of inspection, as would seem by the Committee's report) before the patent boiler was taken in hand, in preparation for the Steam Committee, he (Admiral Tucker) had applied to the Vice-Admiral W. F. Martin at the Admiralty to have a second furnace inserted in the patent boiler to increase its heating power. That request was made on his own responsibility to show the proper working of the patent in the size boiler then under trial. It was forwarded by Admiral Martin to the Committee before the boiler went into the workshop, notwithstanding which, and that the insertion of the

furnace was requested of the Committee in order to ensure a full trial (which the Committee itself admits in page 37 of their Report),* the Committee, who could so clearly see the advantage, refused the request, alleging as a reason, they would "not take the responsibility of an alteration." "As if the responsibility of the result of the addition was not mine, instead of theirs!" says the Admiral. By that refusal a fair trial was of course altogether prevented, nor can the Committee justify their having reported that "the patent boiler was in heating power 25 per cent. under the multi-tubular," after having refused to the former that which they admit would have proportionably increased its heating power, thereby preventing such a boiler as the patentees intended for competition from being tried at all. The permission refused to the inventors of the new boiler was such as is daily accorded to other inventors.

Again, to a second application for another furnace being inserted, the Committee say in their letter to Admiral Tucker of the 12th of July, 1858: "The Committee, without giving any decided opinion how far it is possible to introduce another furnace, as you now propose, into such a small boiler, must decline to make any request grounded upon your proposed alteration. But they will be most happy to witness any trial and give their unbiased opinion, when they go to Sheerness, upon any boiler constructed under your direction, that they may find ready for inspection and use." "A very proper promise of fair conduct after having done me all the injury they could. The only question is,—Did the Committee keep their promise?" remarks the Admiral.

The size of the boiler under trial, into which the patentees desired to insert two furnaces, was large enough to have admitted two of fifteen inches in diameter. In order, therefore, to show that they had not made an ill-considered application, the patentees caused a new boiler of four feet long and one foot in diameter to be prepared, and into that boiler two furnaces were introduced of only four inches in diameter. This boiler was shown the Committee with steam up to 30 lb. pressure, but to give an unbiased opinion, or any opinion at all about it, the Committee altogether omitted. In perfect keeping with that omission, the Committee, although they allude in their report to certain trials which they did not see, are altogether silent on the trial of 144 hours, during which the patent boiler steamed uninterruptedly, while the multi-tubular so often broke down.

The Committee further report of the patent boiler, "it yet required forty-eight minutes more time to raise steam than in the ordinary boiler." The truth of the following table Admiral Tucker offers to prove by undeniable evidence. The trial took place September 1st, 1858.

	H. M.	lbs.	H. M.	H. M.
Patent Boiler.....	Lit fire at 5 25,	Steam up to 74 at 6 40=	1 15	
Multi-tubular	Boiler.....	ditto 9 50,	ditto ditto 10 57=	1 7

The foregoing figures speak for themselves, and they prove the Report of the Committee widely at variance from the truth. The time required to get up steam by the patent boiler (prevented, be it remembered, by the Committee from making its best efforts) did not exceed that required by the multi-tubular by 48 minutes, but only by 8, while it is certain that the trial then made of only three hours, congenial enough to a tube-choking boiler, was in reality utterly insignificant as a test of the best boiler for the

* That as both the grate and heating surfaces would by that means be increased, the power of the boiler to supply steam would be proportionably increased.

Navy. "It will be asked," says Admiral Tucker, "Have I made the Admiralty acquainted with these proceedings of the Committee, and have I challenged investigation? I have. It has not yet been awarded." Were the Report of the Steam Committee only a statement, signed as nothing more than the opinion of the individuals whose names appear, the document would be altogether unimportant, but "An Official Committee" is clothed, as Admiral Tucker says, with so much consequence that their doings should not only be investigated, but exposed; for a decision affecting the interests of an individual being confided to their judgment, it behoves the Committee to be scrupulously fair and just, "and if it be of any—and who will deny that it is of the greatest—importance to our Steam Navy, that it shall be supplied with the best boiler, which in the progress of science may from time to time be produced, it is imperatively necessary that in examination of comparative merits, the commissions and the reports be complete and impartial."

We need not add to these remarks. They show clearly enough, not only that the Steam Machinery Committee appointed by the late Admiralty were a miserably incompetent set of gentlemen, but also that there yet exists at Whitehall an obstructive power of some kind which even the Superintendents and other chief officers of our Dockyards cannot quite break through. Is it too much to ask for a fair and open settlement of this boiler question, which involves financial considerations of great moment to the country?

THE CASE OF HENRY CORT, AND HIS INVENTIONS IN THE MANUFACTURE OF BRITISH IRON.

BY
THOMAS WEBSTER, M.A., F.R.S., &c., Barrister-at-Law.
No. VII.

THE naval authorities appear by the correspondence to have prosecuted the inquiry as to the success of Cort's invention with becoming zeal. On the 1st of March, 1784, the following order was issued:—

"Navy Office, 1st March, 1784.

"GENTLEMEN,—These are to direct and require you to demand from Messrs. Cort and Jellicoe such a number of links and shackles from mooring chains made of neutral iron, according to their own process of working the iron, for an experiment against a like number prepared of the best iron, and to make a trial and report the result of the strength of that made from neutral iron compared with the other. You are to supply them with neutral iron for it if they are in want thereof; for which this shall be your warrant.

(Signed)

"C. MIDDLETON,
J. HENSLOW,
E. HUNT,
G. MARSH.

"To the respective officers of Portsmouth Yard."

The following portion is all that has been preserved of the reply to that order:—

"Portsmouth Yard, 1st June, 1784.

"HONOURABLE SIR,—In obedience to your directions of the 1st of March last, to demand from Messrs. Cort and Jellicoe a number of links and shackles for mooring chains made of neutral iron, according to their new process of working the iron, for an experiment against the like number prepared from the best iron in our smithery—

"We are humbly to acquaint you that we have made the experiments of the links and shackles on two anvils, and letting the large hammer of four cwts. which shuts the arms of

anchors fall the height of sixteen feet on the centre of the links and shackles between the anvils"—

In 1787 was published "A Brief State of Facts relative to the New Method of making Bar Iron with Raw Pit Coal and Grooved Rollers. Discovered and brought to Perfection by Mr. Henry Cort," containing the particulars and results of the experiments on Cort's iron at the dockyards.

The following extracts will be read with much interest:—

"Mr. Cort's process of refining iron from the pig or cast state, in a reverberatory furnace, heated by common coal or any other fuel, has the effect of separating from the metallic particles certain impurities which are not discharged in the common methods of rendering iron malleable; and thereby a manifest difference of quality is occasioned in favour of the furnace iron; which quality is further improved by the mode, also invented by Mr. Cort, and used in manufacturing the iron, when malleable, into bars, and even into bolts, and many uses, by rolling it in a welding heat through rollers with grooves accurately formed, instead of working it under hammers. This iron has a peculiar appearance in its grain, but it is nevertheless so effectually disentangled from impure scoriae, and the texture of it is so uniformly perfect, that it may be pronounced superior, upon the whole, for body, strength, and toughness even to the best of Swedish Orgrounds iron. Mr. Cort manufactured about thirty tons of this iron under the inspection of two Master Smiths belonging to the King's dockyards, from old ship ballast delivered to him out of the dockyard at Portsmouth for that purpose. The bar iron so made by Mr. Cort was afterwards distributed to all the Royal dockyards, and being there wrought into anchors and other naval implements, underwent a series of experiments against the like instruments wrought from the best Orgrounds iron, the marks of which were P L and crown, double bullet, hoop, and L, whereby its qualities were put to the severest test."

The particulars and result of these experiments are as follows:—

RESULTS OF THE EXPERIMENTS AT PORTSMOUTH.

"An anchor of 67 cwts. 2 qrs. 14 lbs., manufactured from Mr. Cort's iron, and tried in the usual way, was found equal to an anchor of the like size made of Swedish Orground iron.

"And P and eye-bolts for ships' caps, tackle-hooks, and hinges for doors, also made of this iron, and top-tackle and snatch-blocks bound with it were equal to the like articles made of the first sort of Orgrounds iron."

EXPERIMENTS MADE AT DEPTFORD DOCKYARD.

"Mr. Cort's anchor was manifestly superior; the part which broke had been injured by some accident in the heating to such a degree as to break short off with little or no strain, and the injury was visible upon inspecting the broken part; but in the second experiment with the arm which had not been so burnt, the anchor opposed to it was torn asunder in a part which had been extremely well manufactured, and where there was no appearance of imperfection or of the iron having suffered the smallest injury, but very much the reverse appeared upon a minute inspection.

"The experiments upon the hooks and strap-pings of bolts, and upon the hooks, eleven in number, were also favourable to Mr. Cort's iron. Six of the articles made of the Swedish iron appear to have been straightened, and only three of those made from his; and two of these three not to the same degree as the Swedish. Three of his indeed broke, and but one of the Swedish.

None of either sort, however, gave way till after they had stood a much greater strain than ever is, or can be, put upon implements of the same kind in real use; and four only of the Swedish iron, but five of Mr. Cort's remained perfect after those against which they were respectively tried gave out. It was one of these five, the hook of a double top swivel block, that stood against one of the same dimensions made of the Swedish iron, which broke, they being equally drawn against each other from opposite capstans, with thirty men heaving at each, a purchase before which both sorts of iron had yielded in the immediately preceding experiment.

"Two eye-bolts of each sort of iron appear to have driven equally well, and two P bolts of Mr. Cort's also drove without injury: but of two perfectly similar made from the Swedish, although both drove, one broke in the stump.

"Upon the whole, it is presumed not too much to assert that in this course of experiments, Mr. Cort's iron was proved to be in every respect equal, at least in quality and substantiality, with the Swedish iron."

EXPERIMENTS MADE AT WOOLWICH DOCKYARD.

"Mr. Cort's anchor was indubitably the strongest; and it may be observed, that although this anchor was the heaviest of the two, yet that was owing to the largeness of the palms, for the shanks and arms were considerably less in circumference throughout than those of the anchor made from the Swedish iron, as appeared by measures taken at a great number of proportionate distances.

"And upon the whole of the trials made here, Mr. Cort's iron appears to have stood completely in five instances, the Orgrounds only in one; his gave way partially in three, the other in four instances; and although that broke also in four cases, his broke only in one. His, therefore, by the comparison of these particular instances may be pronounced superior in strength to the first sort of Orgrounds iron; and workmen in general who have tried it, declare that it is at least equal in all respects, especially that it is rather more malleable, retains its heat longer, welds, and bears punching, turning, and being wrought in the most severe manner to the full well."

EXPERIMENTS MADE AT SHEERNESS DOCKYARD.

"Mr. Cort's anchor was the strongest; and of the rest of the articles, two of his stood and two broke; three of the Swedish stood and one straightened.

"In all these experiments there was a much greater strain as well upon those articles which were not either broken or injured as upon those which were, than is ever applied in the actual use of such instruments on board of any ship."

EXPERIMENTS MADE AT CHATHAM DOCKYARD.

"Mr. Cort's anchor stood, the other was broken; and, in eleven other experiments, Mr. Cort's iron stood, four was injured in four, and broke in three instances. The Swedish iron stood in five, was injured in five, and in one broken; so that there appeared but little inequality, except in the anchor, in which the superiority of Mr. Cort's greatly overweighed the trifling inferiority of it in the aggregate of the other articles."

EXPERIMENTS MADE AT PLYMOUTH DOCKYARD.

"The superiority of Mr. Cort's anchor is sufficiently evident on this trial; of his other articles, two stood, three broke, and three gave way. Of the Swedish, three stood, three broke, and two gave way."

The Master Smith of this yard expressed his opinion that Mr. Cort's iron, used in the articles which were the subjects of the above experiments is equal to any he ever made use of."

GENERAL REMARKS.

"The iron made by Mr. Cort, and tried against the best Swedish iron in the above experiments, was made from old ship ballast, which is a very inferior sort of cast-iron. The Orgrounds iron, against which it was tried, is the best refined, the strongest, and the toughest iron known or ever brought into use before Mr. Cort's discovery; about 20,000 tons of this iron are annually imported from Sweden, and paid for in money at a high price; besides which, about 50,000 tons of bars and slabs are annually imported from Russia; and about 30,000 tons of bar iron are annually made in England. But even if the whole quantity of a hundred thousand tons, one year with another, brought to market in this country in bars, slabs, rods, or other shapes, could be made by our manufacturers without the aid of this discovery, still the best of their iron (not only that which is made at the coke-fineries, but also that which they refine with charcoal, and of which the quantity supplied must always be limited) has not been esteemed of sufficient body, strength, and toughness for anchors, tackle-hooks, the strapping and hooks of blocks, bolts, and other ironwork belonging to the building, rigging, and navigation of ships, upon the perfect goodness of which the lives and safety of so many of His Majesty's useful subjects, the seamen of Great Britain, must depend; only the Orgrounds, imported from Sweden, has been hitherto esteemed sufficiently good to be depended upon for these uses, or to be supplied for the service of Government; but Mr. Cort's iron has been now proved to possess these qualities in a super-eminent degree; and, therefore, the chief questions seems to be, whether it can be manufactured in sufficient quantities, and at a reasonable price. As to the first of these points, although the bar iron at present made in England and Scotland, after the former methods, is not more than about 30,000 tons, as above stated, yet the reason is, that there is no larger demand in the market for iron so inferior in body and strength as much of this is found to be. The quantity of pig iron and castings annually made in Great Britain is not less than about 85,000 tons, which quantity might be very much increased by increasing the number of blast furnaces. At present, they are but about eighty-five in number in England, Wales, and Scotland, but many more might be worked if the encouragement was sufficient by a demand for pig iron equal to what Mr. Cort's discovery must occasion when it is brought into general use, for the raw materials are in a manner inexhaustible.

"The second strong circumstance in favour of this iron is, that even now in the infant state of the manufactory, it may be afforded cheaper than the Swedish iron. It is true that for the purpose of having the iron made, upon which the above experiments were tried, 60 tons of old ballast were delivered to Mr. Cort, and he returned no more than 29 tons 3 cwt. 0 qrs. 16lbs. in bars; but the bad quality of that metal, and the quantity of rust and dirt adhering to it, whereby the weight was increased, and some other circumstances disadvantageous to the yield, afford ample reasons why this should not be taken as a just criterion in that respect. For instance, some of the ballast was in large pieces, 5, 6, and even 7 cwt. and of such forms that it was impossible to break them; so that it became necessary to melt and run some of them down into pigs before they could be put into the finery-furnace. Others, which were put at once into the refinery furnace, were unwieldy, and therefore were both melted and worked with difficulty, and a very extraordinary waste. But added to these observations, the fact is ascertained, that in a regular course of working the

refining furnaces, three men—two at work together, and the third taking his rest in turns—can with ease refine 4 tons of pig a-week from one furnace, which being afterwards rolled into bars at one welding heat, will produce bar iron of even the smallest dimensions (which might, if required, be also slit into nail rods, at the same heat in which the bar is first formed, and consequently without any sensible additional expense) of the quality above described, in the proportion of upwards of a ton from every 32 cwt. of pig, the quality generally used at the coke fineries, in making a ton of the largest size of mill bar iron.

"It may be further observed, that such bars as are required to be feather-edged, for the laying of shanks of anchors, are originally manufactured of that shape, and of dimensions exactly proportionate throughout, by means of Mr. Cort's rollers; and a saving is thereby occasioned of the fire and labour necessary to prepare Swedish bars into that form, and of the waste in heating and hammering, in order to fit them (though by far less perfectly) for the same use.

"And, upon the whole, notwithstanding the expenses unavoidably incident to such a discovery in its infant state, this iron can be afforded at a cheaper price, to be paid and circulated at home, than has hitherto been necessarily paid to foreigners, for an article so very important to Government and the nation, as the first sort of Swedish Orgrounds iron, upon which the preservation of His Majesty's fleet hitherto depended, but to which the iron manufactured according to this discovery has been proved equal for use in all respects, and superior in many particular instances. Among these, it cannot escape observation, that in all the five different trials upon large anchors, weighing from 34 to 59 cwt., those made of the furnace-refined iron had a manifest superiority over those made of the Orgrounds iron. In all these cases respectively, the anchors made of the two different sorts of iron were drawn equally against each other, with a purchase which it is almost incredible that either should have borne, before either gave way; and notwithstanding those made of the Orgrounds iron did give way at last, in all the trials, yet it was not till after standing a strain much greater than any other iron could have borne, or than the hardest actual service can be expected to require."

These elaborate experiments and severe trials, conducted under such varied circumstances and conditions (the details of which are fully stated) in all the royal dockyards, led to the conclusion that Cort, by his method of puddling and working by grooved rollers, could make, out of the worst material (ship ballast iron) an iron equal, and in some cases superior, to the best Swedish iron.

THE NATIONAL DEFENCES.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—Perhaps you will allow me to state in your widely-circulated scientific miscellany, for the information of those gentlemen who are now proposing plans for the fortification of London, that I can suggest, and have long since made known to the Admiralty and the Government, the means whereby all the central and densely-populated portions of London, Paris, St. Petersburg, or any other large town, or a fleet of vessels in harbour, might, to a moral certainty, be speedily destroyed from a distance of ten miles and upwards if required, and comparatively, as regards all other modes of warfare, at a very trifling expense.

W. H. JAMES, C.E.

London, August 2, 1859.

REPORT OF THE ADMIRALTY COMMITTEE ON DOCKYARD ECONOMY.

THE Report of the Committee appointed by the late Admiralty to investigate the subject of Dockyard economy has come into our hands. It has not yet been presented to the House of Commons, and it cannot therefore be obtained through the ordinary channels of publication; but we have contrived to secure copies privately, so to speak, and doubt not that our readers will be glad to learn their contents without questioning the means by which we have possessed ourselves of them. As we shall have occasion to discuss this strange production elsewhere, it will be sufficient for us here to present the following "Recapitulation" of the substance of the Report, and the various recommendations which the Committee make. The Committee consisted of Rear-Admiral Smart, K.H., Mr. H. Chatfield, Master Shipwright of Deptford Dockyard, Mr. Andrew Murray, Chief Engineer of Portsmouth Dockyard, Mr. Robert Laws, Storekeeper of Chatham Dockyard, and Mr. Robert Bowman, "Civil Engineer and Ship-builder," of 17 Paynton-terrace, East India Road. Mr. Chatfield has refused to sign the report, and appended a lucid statement of his reasons for withholding his name from the production of his colleagues. For the succeeding remarks he is therefore in no way responsible; all the credit, and all the disgrace of them belong exclusively to Admiral Smart, and Messrs. Murray, Laws, and Bowman. The recapitulation is as follows:—

The committee recommend that a *shipwright and an engineer officer attached to the Surveyor's department should visit the Dockyards and factories more frequently** for the purpose of promoting greater uniformity in the interpretation of orders, and in the mode of carrying on the work in the fitting and equipment of ships, and to explain the desires of the Board and of the Surveyor, when not fully understood.

They recommend that the *morning meeting* of the officers should be conducted in a manner to be of more service for communication and proper concert in carrying on the business of the yard than is the case at present.

They have made some remarks on the *sub-division of the supervision* as at present carried out amongst the chief professional officers of the Dockyards, and they have recommended that those officers and those branches which can best execute any work that is required, should be the parties to execute it, and that those officers who best understand the nature of the work should have the supervision of it. This will reduce the number of petty branches, by doing away with one wherever there are two separate workshops of the same trade in the Dockyards and factories. The division of responsibility, for the execution of the work, which is objectionable, but which has hitherto existed in the saw-mills, and other branches where machinery is employed, is also proposed to be done away with, by placing the men, as well as the machinery, under the charge of the chief engineer for the execution of any work that may be required by the shipwright department.

The Committee consider that the shipwright officers have devoted their time and attention too exclusively to the execution of work of the best quality, and within the shortest possible period, and that they have too much overlooked the question of *the cost of the work produced*. The fact that upon some urgent and pressing occasions cost is no object whatever in comparison with rapidity of execution, appears to have led them away from the due consideration of cost for production of ordinary work in ordinary times.

* These italics, and others which follow, are employed to facilitate reference to this document hereafter.—*Eds. M.M.*

The want of a proper stimulus to Government officers for the efficient and economical management of the works under their charge being very apparent in the Dockyards, the Committee have recommended that the *cost of every ship built* for ordinary, or completed for sea, and the balance sheets of the chief manufacturing branches, showing the net cost of the work produced in the different Dockyards, should be printed annually with the Navy Estimates, and presented to Parliament, and circulated to all the Dockyards. If this were done, those officers who produced the work at the cheapest rate would have credit for it, and any officer who allowed the work of his department to cost too much, would be brought to account. Private manufacturers, also, would have an opportunity of judging whether the Government works were conducted satisfactorily or not, and would check any excessive cost.

The Committee found that the *offices for the foremen or leading men* immediately supervising the men in the different workshops were not generally well arranged to enable them to see their men while at work, and many of the shops themselves were badly arranged in this respect, and were lumbered up with material. They recommended that immediate steps should be taken to remedy this evil.

The Committee have given much attention to the subject of *superannuation to the workmen* of the Dockyards, and they are very strongly of opinion that the present system has an injurious effect upon the service, tending to protect an inefficient man and prevent him from being discharged, because the supervising officer considers that after he has served a few years he has a claim upon the service, and that he would lose this by his discharge. The wages paid to the Dockyard men are considered to be lower than those paid to men in private trade, and partly on account of their future superannuation. A feeling, therefore, exists that they are deprived of something which they have earned, and which is their due, if they are discharged; and this leads to an unwillingness on the part of the officer to recommend them to be discharged, or even to report them to their superiors for misconduct, lest this report should lead to that result. The Committee have recommended that for all future entries of workmen in the yards a system of deferred annuities should be adopted, so that every man on his discharge would take his annuity policy with him, and continue it thereafter or give it up at his own option. By this system the officers would be perfectly free to discharge inefficient or badly-conducted men at any time, and the men would have no cause of complaint: the annuity policy to be withheld if the man left the yard in the time of war, or time of pressure, when his services were required in the yard, and when other men could not be obtained.

The Committee have considered the working hours of the yards, and have proposed considerable modification in them. In addition to some other minor alterations, they have arranged a new table of working hours, so as to allow the men one and a half hours exact stopping time for dinner during the whole year, except on Saturdays, and thirty-five minutes stopping time for breakfast, except during seven weeks of the shortest days. The men, at present, are not allowed to stop for breakfast even in the summer time, which the Committee consider to be a very objectionable arrangement. They have also arranged the hours so that, without lessening the number of hours worked per week during the greater part of the year, the whole of the men of the Dockyard should leave off work on Saturdays at four o'clock. The Committee believe that these arrangements will be agreeable and beneficial to the men, and that they will also be beneficial to the Government, as the total number of hours worked in the year will be increased. The next subject treated of by the committee is that of the *entries of men*. They consider that the present arrangements have failed to secure in all cases the entry of the best men that could be obtained. They have pointed out

in detail the modes which they would recommend for the entries of the names of candidates for employment, and they have prepared forms and certificates to guard against the entry of inefficient men or of any man inferior to any other who may be a candidate. They believe that if these forms are strictly acted up to and enforced, they will produce the effect desired. The Committee have also recommended the *entry of a greater number of boys* into the yards, and have pointed out where they may be employed with advantage.

The Committee have found that the *systems of promotions* have not been working in such a way as to ensure the appointment of the fittest men to the vacant situations. They have, therefore, proposed some alterations in the arrangements, and that the examination papers for the professional officers should be issued from the office of the Surveyor of the Navy under arrangements which they conceive will not throw much, if any, additional labour on his department, and will ensure uniformity at the yards. They found that by the present system of examination too little weight was given to practical experience and other points in the character of a man to fit him to be a good supervising officer, which could not be tested by any examination, and the possession of which tends to the want rather than otherwise of such knowledge as would enable him to be successful in a competitive theoretical examination on paper.

The Committee have also taken the liberty of referring to the *annual visits of their lordships* to the Dockyards and the master of the workmen, and they submit for consideration whether this should be continued, with the half-holiday to the men thereafter, at a cost of about £1,370 for all the yards.

The Committee have given much consideration to the three systems under which the payments are made to the workmen for their labour on work performed at the Dockyards. The first system is termed *task and job*, by which a definite sum of money is paid for each specific piece of work in detail according to an established scheme of prices without defining the whole sum for which a ship or structure is to be completed. The second system is known at the present day as "*day pay under check measurement*," and is nearly the same as that formerly known under the term of "*task and job, limited earnings*." Under this system, the men are employed on a fixed rate of day pay, and the work performed by them is measured and valued weekly, by the scheme of prices for task and job work, and the men are paid the amount of their week's pay if the value of the work is equal thereto, but if a greater quantity of work has been done, and its value exceeds this amount, they are not paid this excess of earnings, and thus they are not paid for the whole of the work which they have performed, while if the value of the work falls short of their week's wages, they are mulcted to the extent of the deficiency, and do not receive the full amount of their fixed day pay. The third system is the employment of the men on *day pay*, depending upon the supervision of the officers for the exertions of the men, and, therefore, for the quantity of work performed. The Committee have shown in their Report that the system of task and job has been subject to much abuse. *Sister corvettes* of 1,462 tons, costing upwards of £3,000 more for shipwrights' labour in one yard than another, though both were paid for by measurement of the work upon them, under the same scheme of prices, and though the work upon both must have been nearly identical; and they have also pointed out other cases of similar discrepancy. They have also shown that the system of day work under check measurement is injurious to the service, as checking the energies of the men who know the prices for each piece of work and value the work as it progresses, and do no more than is sufficient to cover the amount of their weekly wages; and that done, they feel, and tell the officers, that they have no right to exact more. The Committee have recommended the discontinuance of both of these last-mentioned

systems, and that all new ships should be built on a system of piecework, defining the price for the whole ship as in private trade. They are of opinion that one of the assistant-surveyors, and an intelligent assistant-master shipwright would require to be directed to make themselves acquainted with this system, as worked in private trade; and that a foreman from a private trade, accustomed to it, should be engaged to introduce it first into one of the yards, and subsequently into the others. The Committee make this recommendation because they attribute the failure up to the present time of obtaining for the Government under task and job work the same advantages that accrue in private trade from the system of piecework to the want of a proper knowledge of how to work it. The Committee consider that all work to which this system cannot be applied should be done by day work under proper supervision; and that all work should cease as soon as possible to be performed under the present system of task and job. The experience of every day confirms the Committee in this opinion, and they would recommend that the leading men should be arranged as soon as possible in the positions recommended in the report, and that all the men should be put upon day work with extra hours, till the arrangements are completed for building new ships by the system of piecework as recommended.

The yards are at present worked under the system of task and job, and the cost of the staff of measurers at present employed amounts to the large sum of £15,262 per annum. This is in addition to the ordinary supervision, and for a staff of non-productive men. The cost of the ordinary staff of measurers, with their writers, messengers, &c., is £5,250, as provided for by last year's navy estimates. By the system proposed by the Committee these sums will be entirely saved, and all the advantages of piecework will still be secured to the Government on all new work and extensive repairs. Eight of the *corvettes* before referred to cost, for shipwrights' labour, without fitting for sea, 109s. 8½d. per ton, and one fitted for sea cost 173s. 11d., while it was stated in evidence to the Committee that a corvette, if built in a private yard, with scantlings, fastenings, and workmanship similar to ships in Her Majesty's navy, fitted for sea, would be about 52s. only per ton for shipwrights' labour. Allowing for any superiority of workmanship in the Dockyard, or other difficulties, the Committee can see no reason why ships should not be built for a price in the Dockyard at least approaching to that paid in private trade, if the same system of working the men as now recommended be adopted, instead of their costing, as in the case quoted above, more than three times as much.

With respect to the present *shipwright officers* the committee are of opinion that there are too many grades, and that a want of clearness exists in defining the duties of each grade. They consider that the present *leading men* are in a false position, sharing in the earnings of the gang of men to which they belong when on task and job, and expected to perform the duties of a supervising officer on behalf of the Government. The Committee have commented fully upon this in their Report, and they recommend that the position and pay of the leading men should be raised, and that the class of inspectors should be done away with. They also consider that the *foremen* are more in number than are necessary. By the supervision as proposed by them in their Report, and which they feel confident will be sufficient and superior to the present system, an annual saving in salaries to these classes of officers will be effected to the amount of £9,463 per annum. The Committee have laid down definite rules for the *appointment of leading men and foremen*, which will ensure greater practical experience in these officers than has hitherto existed in all cases.

The Committee have also made arrangements respecting *draughtsmen* for the mould loft, who require more education; and they have made

arrangements for their promotion separately from the more practical officers.

The Committee have given much attention to the subject of providing for a future supply of men, properly educated, to be fit to fill the position of the *superior officers in the shipwright department*. All the officers of the late school of naval architecture are now well advanced in years, and the want of properly-educated successors is becoming seriously apparent. At the last examination for assistant master shipwrights, not one of the candidates came up to the very moderate standard of scientific knowledge laid down as necessary by their Lordships' circulars of 1847 and 1858. The Committee have made recommendations respecting the promotion of the better educated and superior men from the class of workmen, and have at the same time recommended the introduction of *superior class pupils* to be trained in the dockyards, but without entailing any expense in the form of schools or professors, the number required being so limited. They have recommended the entry of two such pupils at once, two in three years, and one in every third year thereafter, which will be sufficient, with the superior men rising from the ranks, to fill the number of positions as assistant-surveyors and masters-shipwrights, and their assistants at the yards. The Committee consider that none but these last-named officers, about twenty in number, required to be possessed of superior scientific acquirements, and to be men of general knowledge and general experience; and that all these officers should be looked upon as superior officers, and distinctly marked from the grade of foremen, who should be experienced practical men. The Committee have, therefore, recommended that a clearer line than hitherto should be drawn between these classes of officers, in the same manner as between the commissioned and non-commissioned officers of the army and navy.

Respecting the *joiners' department*, the Committee have made some recommendations with a view to improve the supervision, and have recommended the increase of the use of machinery in that department in some of the yards.

The *wheelwrights department* was found to require improvement in most of the yards, both as regards supervision and machinery.

The Committee have recommended the entry of *more painters*, instead of continuing the practice of employing labourers to such an extent as has hitherto obtained.

With regard to *labourers*, the Committee consider that the supervision over them hitherto has been far below what is required, and they recommend the appointment of two foremen, under the boatswain of the yard. They also recommend an increase of wages to the labourers, as they are satisfied that the wages of 13s. per week, as now given, are not sufficient to maintain a man in proper working condition if he has a wife and family depending upon him. The Committee found the complaint general that there were not enough labourers to save the employment of skilled artificers at high wages to do labourers' work, and they have recommended that labourers be added to the different workshops, and that two labourers should be attached to, and form part of, every gang of shipwrights, to fetch stores and remove chips, shavings, &c. They also recommend that *scavellers* be re-introduced to work for the shipwrights, erect stages, assist in getting heavy weights on board ships, and other work.

The Committee recommend that the *saw mills*, as is the case at Chatham, the *millwright shops*, and the *smitheries* at all the yards, and the *block mills and distilling apparatus* shop at Portsmouth should be placed under the chief engineer, for the reasons before referred to.

The Committee have made recommendations for improving the efficiency of the *metal mills at Chatham*, as also the *lead mills* there.

The Committee recommend that the *East Ropery at Devonport* should be converted into a spinning mill, in addition to the increase of the spinning machines at Chatham for spinning yarn by ma-

chinery for the whole service, and that the laying machinery at Chatham and Devonport should supply the whole service with rope. The expense of the separate establishment at Portsmouth would thus be saved, and the building would become available for other purposes for which it is much needed, and which are pointed out in the Report.

The Committee recommend that more complete housing should be built over those *ships placed in ordinary*, and that those ships intended for ordinary should be so fitted and be kept in ordinary as long as there are any other vessels of the same class not so fitted which are available for service.

The Committee recommend the use of chain cable instead of the long-linked mooring-chain for the moorings of the ordinary, as being both more economical in itself, as shown by the details given in the Report, and much more easy and economical to work.

The Committee recommend improvements in the means of *locomotion in the yards*, and that a more definite system of ordinary rails should be laid down in all of them capable of taking locomotive engines, but without use of them for the ordinary traffic. They consider that these rails would be more advantageous than tramways or traction engines.

With respect to the *dockyard schools* the Committee have made several recommendations. They consider that no boys should be selected above their companions to receive a superior education, and then, be expected to return to their work thereafter as mechanics. They recommend that the school-room should be opened gratuitously in the evenings to a limited number of men as well as boys, and that the schoolmasters should then act in the same manner as private tutors to those who may be attending, giving instruction to each individually, and not as a class.

With respect to the *clerks of the dockyards*, the Committee consider that the examination before entry should include mensuration of surfaces and solids, as their duties require them to take the measurements of works and of timber and other materials. The Committee also consider that the discipline of the clerks in the offices is not in a satisfactory state, and they therefore recommend that the signing of the declaration enforcing obedience to all senior to them in their department, as required by the instructions, should be attended to at all the yards. Clerks appear also to have been promoted by seniority alone in some cases, and without reference to the opinion of the officer under whom they were serving, which is prejudicial to the service. The Committee have found that the quarterly certificate that the conduct of the clerk had been satisfactory during the past quarter, before he is to receive his salary, has in some yards fallen into disuse, and they consider that it has failed in being useful by being too severe. No superior officer is inclined to deprive a clerk of his whole income by taking upon himself to refuse to sign this certificate merely because the clerk has not been so diligent as he might have been. The Committee have therefore recommended, in lieu of this certificate, that a certificate should be required from every chief officer under whom a clerk may be serving, before he receives the annual rise of pay due to his position, stating that his conduct and attention have been satisfactory. The Committee are of opinion that this power in the hands of a superior officer will be duly exercised by him, and will be productive of much good; but the refusal of the certificate should not be looked upon in too serious a light by the authorities in London, and lead them to believe that because it is refused an inquiry should therefore be made whether the clerk should be retained in the service; because, in that case, again, the strenuousness of such a measure would make the superior officer hesitate to refuse the certificate, and the object of stimulating any young clerks who are capable of exertion, but who have only been idle or indifferent, would be lost.

The Committee have recommended a man of

better standing than the present *leading man of storehouses* to be placed over the stores, to attend especially to the issues, as the clerks in the storehouses are occupied in their duties in the offices, and cannot attend to this duty personally.

The Committee found generally a want of attention to keeping up a store of properly *seasoned material*, especially for joiners' use and for wheelwrights' use, and they recommend greater attention to this point.

They consider that the *contracts and schedules* require revising, as well as the standard patterns. They have made remarks in their Report on several points connected with the receipt of stores, especially as regards the chemical analysis of copper, paint, &c., at Chatham, the repair of articles for store, the preservation of stores—especially made masts and mast timber—and the appropriation of obsolete stores.

With respect to the *Director of Work's department*, the Committee recommend more concert with the department who are to use the buildings about to be erected; and they show reasons in the Report for this recommendation.

They recommend an alteration in the system of taking the *local contracts*, so that the Government material may be more largely used; and they recommend the engagement of a few workmen, under the clerk of works, to be employed on small jobbing work, now done by day-work by men under the contractor.

With respect to the *factory department* the Committee recommend that the men should be continued as hired men; but that a system of deferred annuities should be introduced, free from the objections to the present system of superannuation for the Dockyard men. They do not recommend the introduction of task and job work into the factories. They recommend the printing and appending the balance sheets to the navy estimates to give a stimulus to the officers to conduct the works under their charge economically. They recommend greater control to be exercised over the stock of stores in the factory storehouses by the storekeeper of the yard, and over the cash payments of wages of the factories by the accountant of the yard. They recommend additional supervision over the factory at Sheerness. They recommend more definite pay and position to the junior superior officers of the factories, and that the qualification of those officers should be more thoroughly tested before they are appointed.

In conclusion, the Committee remark "that many of the recommendations submitted by them are not supported by the evidence of the officers of the Dockyards; but they are in accordance with the practices of private trade." They finish by saying:—"The Committee have had occasion to point out many alterations, but they have proposed no changes where they did not think them necessary for the improvement and the future well-being of the service in the Dockyards, and they feel that wherever they have pointed out faults, these faults are to be attributed more to the system as a whole than to the men. Errors and faults will gather and increase with the age of every establishment, and few establishments of such old standing as the Dockyards will bear comparison with private establishments of the day; but it is the comparison which the Committee have endeavoured to bring to bear upon them; and they think that credit will be given to them for having had no other object in view in their remarks than the benefit of the service."

The following paragraph is going the round of the newspaper world:—"The Austrian (American) telegraphist, Mr. Hughes, has added another great improvement to the science of telegraphy. He has invented a telegraph which at once supersedes the whole system of telegraphic signals as now in use. The new instrument, without causing more wires to be used than at present, transmits messages, indicating those messages to the eye by the ordinary letters of the alphabet. The advantage of the instrument is, that it can be used by any person who can spell a message. It is small and portable. Any railway guard may carry one in his pocket." We need only say we do not believe this.

entire absence of smoke with the Benwell pit coal.

The steam is maintained at 60 lbs. per square inch above the atmosphere, and the engine is usually worked with the steam cut off at one-fifth of the stroke. The main slide, *P*, having always exactly the same motion, whatever be the degree of expansion, the opening of the exhaust and the amount of compression are constant. The usual speed of the engine is 24 revolutions per minute, or 192 feet per minute speed of piston; but it has been worked up to 40 revolutions, or 320 feet per minute of the piston. The pressure of water upon the pumps as indicated by a pressure gauge is 80 lbs. per square inch when standing, and rises to a mean of about 95 lbs. per square inch whilst working, equivalent to 18.6 lbs. per square inch effective pressure on the steam piston, or 57 horse power effective. Taking the coals consumed for 3 months, the consumption is 30 cwts. per day of 12 hours, including lighting fires, &c., or 5 lbs. of coals per effective horse power per hour, and 4 lbs. per indicated horse power per hour. It will thus be seen that the consumption of coals is not much more than if this engine had been a condensing one, whilst the first cost of the engine and building is much less, and the smooth and steady motion of the machine is much in its favour when compared with the beam engines.

BREAKWATER AT THE PORT OF BLYTH.

By MICHAEL SCOTT, C.E.

(Concluded from p. 72.)

THE author does not recommend the plan of depositing rubble up to low-water mark, and then erecting upon this a wall either of stone, or timber and stone, considering such an arrangement to be incorrect in principle; but he does recommend that the wall be built from the bottom, or from about 15 feet below low-water. No doubt the first-mentioned plan has been adopted, chiefly on account of the difficulty and expense of building under water, but the author hopes to show, that these need no longer be regarded as such formidable objections. In the system hitherto adopted for building piers under water, the operations have been confined to one end of the work, and the progress has, consequently been very slow, the pier at Dover, for instance, advancing only at the rate of 100 feet per annum. This slow progress is mainly to be accounted for by two great obstacles to the operations of either helmet-divers, or of bells, which are current and ground swell; and with respect to the former, the further the pier projects the more rapid is the current past the end likely to become; indeed, in some cases, the scour might endanger the stability of the work. Now, it will be observed, that in facing an existing pier, the work might proceed with great rapidity, for it might be carried on at a number of places at once, and there would be little, if any, current to interfere with the operations.

To illustrate the advantages in these respects, the author will describe the method proposed by him for completing one form of the permanent work. Suppose the form of breakwater shown in Fig. 4 to be selected. Frames are sunk at intervals of 30 feet, and stand on the natural bottom. Rails being laid on barks of timber between these principals, rubble is tipped from waggons to form the bank, of the dimensions shown, up to a level of 17 feet below low-water; and the intermediate frames are then erected upon it, leaving spaces of 5 feet. On the outside of these frames, above low water, planks are attached, and are secured by pieces of timber bolted through to the frames. The object of placing them on the outside is to allow of their being easily removed afterwards. Below low-water, the spaces are filled in with panels, or vertical pieces, secured by the sliding ties, as shown in Fig. 5. The interior is then filled with rubble, up to 6 feet above high-water, and covered with an open flooring of timber. On the sea side, a parapet is carried up, and there is then a breakwater sufficient to last for many years. For the purpose of forming the permanent stone face, the projecting portion of the rubble bank is

to be levelled, and upon this large blocks are to be laid. With regard to the composition of these blocks, on the author's system, even when the mass of the block was composed of ordinary material, the face exposed to the sea would be hard and impenetrable, and yet the evil of a distinct line of demarcation between the face and the body of the block would be carefully avoided. As these blocks are deposited, the planking is to be removed, and the space between the face-work and the original rubble heart is to be carefully filled. There are some peculiarities in the method proposed by the author for setting these face-blocks. It may be stated generally, that the main objects in view are, first, to afford increased facilities for handling heavy masses, and secondly, as a considerable part of the faces must be built under water by divers, to place within easy reach of these men the power of moving the stone in every direction, without the necessity of communicating with any one above water.

It has frequently been proposed to employ large concrete masses in the building of piers: one principal reason which suggests itself to the author for this idea not having been extensively put in practice, is the difficulty of handling such great weights. As has been stated, not only must the staging be of great strength, but the crane gearing to deal with say 25 tons must be cumbersome and expensive. As regards hydraulic machinery the difficulty is to arrange it, so that it shall not be still more so. Now as the author proposes to deal with masses weighing more than 25 tons, it is essential to devise some method of moving them, and the following is the result:—With the aid of bars, divers can do something with blocks weighing from 5 to 8 tons, as so much of the weight is neutralized when they are immersed; but even with these, when laying a face course, it requires the signal-man to act in perfect unison with the diver, or time is lost. It will be observed that, in the case under consideration, the work consists only of face courses, and is composed of blocks of such weight, that so far as any direct action on the mass is concerned, the divers would be nearly helpless. Hence arises the necessity of employing some new means by which the diver would be able to move the blocks in every required direction. This involves six distinct motions—down, up, forward, backwards, to the right, and to the left. The apparatus* which the author proposes to employ may be briefly described as follows:—There is a traversing frame, with one end projecting over the side of the pier. This frame moves by means of wheels upon four lines of rails. Upon the inner end of the frame is placed an accumulator (which was patented by the author in 1851), which serves at once as a reservoir of power, and a back balance. Upon the front end of the frame, there is a cross frame carrying a crab. The operation of depositing a block is performed thus: the block is conveyed on a wagon under the traveller; the crab is over head, and instead of the chain being attached directly to the mass, a cylinder containing a piston is interposed, the cylinder hanging from the chain, and the piston-rod being connected to the block. A flexible tube from the lower end of the cylinder communicates with the accumulator, and a stop-cock being opened, the water flowing from the reservoir under pressure forces up the piston, and lifts the block. When thus suspended the crab is moved, by means of a rack and pinion, to near the end of the frame, and then, with the aid of the break, the workmen lower the block until it rests on the previous course. He then fixes the break, and the mass is consigned to the care of the divers. If the diver wishes to raise the block, he opens the communication between the accumulator and the cylinder, and the piston is forced up. When the block is raised far enough, he shuts the cock, and it remains suspended. When it is desired to lower the block, a second cock is opened in the

same tube placed between the first and the cylinder which allows the water to flow out of the latter and the mass descends. If the block is to be moved laterally, the piston of a small cylinder fixed to the framing above is attached to the crab by means of a chain passing over a pulley, fixed on the opposite end of the frame. This cylinder is connected directly with the accumulator by means of a tube, and the communication being always open, the tendency is always to draw the crab to the left. Another cylinder is fixed in the opposite direction, and connected to the crab in the same manner. This cylinder also communicates with the accumulator, and being larger in diameter than the former one, when the communication is opened, it draws the crab from left to right, and the water in the first cylinder being forced back into the accumulator, there is no loss of power arising from the use of the first cylinder. The tube connecting the second cylinder with the accumulator passes down to the divers and up again. When the crab is to return to the left, the communication between the second cylinder and the accumulator is shut, and another being opened, the water is allowed to flow out, the small cylinder pulling the crab back. The motion forward and backward is communicated in the same way.

It will be seen that by means of three tubes within reach of the divers, motion in every direction is obtained, without the necessity of communicating with any one above water. It is thought that by the means now described the great difficulty of signalling is overcome; for that difficulty does not consist so much in indicating the direction in which the motion is required, as the amount of that motion. This becomes of more than ordinary importance in the case of large blocks, which men cannot easily swing from the perpendicular.

For moving the great frame, a long cylinder, of small diameter, is fixed at each side of it; the piston-rods are hooked on to chains made fast to the forward end of the work, and the water being admitted as before, the frame is moved forward. When the piston reaches the end of the stroke, it is drawn out and is again hooked on to the chain; this can be easily effected by continuing downwards for a few feet the tube which empties the cylinder, as it tends to produce a partial vacuum.

THE COMMISSIONERS' OF PATENTS REPORT OF 1858.

THE Commissioners of Patents appointed under the Patent Law Amendment Act, 1852, (15 & 16 Vict. c. 83.) in compliance with the terms of the third section of that Act, make the following Report of their proceedings under and in pursuance of the same for the year 1858, in continuance of their Report of proceedings for 1857.

The number of applications for provisional protection recorded within the year 1858 was 3,007; the number of patents passed thereon was 1,954; the number of specifications filed in pursuance thereof was 1,880; the number of applications lapsed or forfeited, the applicants having neglected to proceed for their patents within the six months of provisional protection, was 1,047.

The Act 16 Vict. c. 5. enacts that all Letters Patent for inventions to be granted under the provisions of the Patent Law Amendment Act, 1852, shall be made subject to the condition that the same shall be void at the expiration of three years and seven years respectively from the date thereof, unless there be paid, before the expiration of the said three years and seven years respectively the stamp duties in the schedule thereunto annexed, viz., £50 at the expiration of the third year, and £100 at the expiration of the seventh year.

Two thousand and forty-four patents bear date between the 1st July 1855 and the 30th June 1856; the additional stamp duty of £50 has been paid on 568 of that number; and 1,476 have become void by reason of non-payment.

All the provisional, complete, and final specifications filed in the office upon the patents granted under the Act have been printed and published in

* For drawings of this apparatus see "Report of the Commissioners, &c., on Harbours of Refuge," vol. I., Plate 3. Folio, London. 1859.—M. S.

continuation, with lithographic outline copies of the drawings accompanying the same, and within three weeks of the respective dates of filing, according to the provisions of the Act 16 and 17 Vict. c. 115.

The provisional specifications filed in the office and lapsed and forfeited, have also been printed and published in continuation.

Printed certified copies of the specifications filed in the office, as also certified copies of patents, and of the record book of assignments of patents and licences, with copies of such assignments and licences, have been sent, in continuation, to the office of the Director of Chancery in Edinburgh, and the enrolment office of the Court of Chancery in Dublin, pursuant to the Act of 1852 and the Act of 16 and 17 Vict. c. 115.

The work of printing the specifications of patents under the old law, 12,977 in number, and dating from 1711 to 1852, having been completed, the Commissioners of Patents have directed short abstracts or abridgments of specifications, grouped under the different heads of invention, to be prepared and published; for example, abridgments of the specifications of patents relating to the propulsion of vessels, commencing in the year 1618 and ending 1857, comprising nearly 1,000 inventions, have been published in three parts, making one small volume.

Abridgments relating to the following subjects of invention have also been published:—Drain tiles and pipes; manufacture of iron and steel, 3 parts; manures; sewing and embroidering; preservation of food; aids to locomotion; steam culture.

Other series are in the press, and it is intended to publish at the rate of six or eight series in each year, completing the work in eight or ten years.

These abridgments are sold at prices a little above the cost of printing and paper.

To the above Report is appended the Report of the Commissioners of Patents on the subject of the building of a patent office and a public library which has been transmitted to Her Majesty's treasury, together with the annual financial papers of the office.

IMPROVED SIGNAL LAMPS FOR THE NAVY.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."
17 Gullford-road, South-st., Greenwich,
2nd August, 1859.

GENTLEMEN,—In 1856 I took out a patent for improvements in ship signal-lamps, pier-head lights, &c., and having on the 28th ult. taken out through you another patent for further improvements of the same, and lighthouses generally, I beg through your valuable journal to give a brief description of the merits of my new patent.

I am, Gentlemen, yours obediently,

J. WEIR D. BROWN,

Late Demonstrator of Anatomy at the London Hospital.

In the first place I beg to say a few words on the subject of my former patent, all the lamps manufactured under which are constructed of square lenses shaped in such a manner that at the edges where they join their fellows lenses are formed, so that the whole extent of glass consists of combined *diffusing* lenses, and when the lamps are lit many points of power are obtained, which causes the light to become larger, more powerful and brilliant, and thereby penetrates through a haze when the ordinary lights are invisible, which is the critical time when a light is of value for the prevention of collisions, loss of life and property at sea. The power of my lamps has been fully proved at trials ordered by the Board of Admiralty, Trinity, &c., &c., and I crave your indulgence by allowing the enclosed reports on their merits to be inserted:—

H.M. Victualling Yard, Deptford,
8th November, 1857.

SIR,—Having on the 27th and 31st ultimo witnessed from this Yard the signal light in the lamp of your invention, when displayed with one of the

pattern now in use in the Navy, near the Observatory at Greenwich, I have no hesitation in saying that in both instances the brilliancy of your light greatly excelled that of the other, more particularly so on the latter occasion, when the haze rendered it difficult to distinguish the Navy lamp with the aid of a glass, whilst yours was very distinct to the eye.

I remain, Sir, your obedient servant,

E. J. P. PHARN, R.N., Master Attendant.
Mr. J. W. Brown, 25 Wickham-terrace, Deptford.

R.M.S.N. Company's ship Tamar, Southampton,
8th June, 1859.

Captain Vincent, R.N., Superintendent.

SIR,—I have much pleasure in being able to report most favourably of the mast-head lamp put on board Tamar previous to her last voyage.

I have tested it against our own lamp, and although Dr. Brown's is smaller, yet the light is much more brilliant, and can be seen a considerable distance further in hazy or foggy weather. The lamp also wanted no trimming, and was as bright after eight or ten hours burning as when first lighted; so much pleased was I with it, that after leaving Lisbon I used it entirely, as I considered that by being seen so much further it might lessen the chance of collision.

I hope I may be allowed to retain Dr. Brown's lamp.

I am, Sir,

Your most obedient servant,

(Signed) JOHN H. JELlicoe, Commander.

My new patent consists in constructing lamps, lighthouses, &c., out of tiers of lenses placed one above the other, the perpendicular edges of which are so mitred that they join their fellows like the key-stones of an arch, and according to the angle at which they are mitred so a circle or half circle of any extent can be formed.

For the sake of illustration I take a lamp showing half a circle, constructed of three tiers of lenses, each tier consisting of 10 plano-convex lenses shaped on my plan, so that where they join their fellows lenses are formed. The interior will present a series of 45 distinct flat surfaces, 15 to each tier, without metal work separating them. The external appearance will be half spherical, the lenses of each tier being so blended one with the other that no depressions exist between the several lenses which can cause a break in the light.

Having as briefly as possible described the construction of the lamp, it will be seen that I get in contiguity forty-five distinct and direct powers of light, which all become, if I may use the expression, so amalgamated that the result is a more considerable increase of size, power, and brilliancy of the light than is possible to be obtained from a lamp or lighthouse constructed of one large lens or piece of glass, because the power of the light, although the lens may be well filled, becomes weakened from the centre or focal point having to supply so great an extent of glass. This point has been clearly proved at the different trials of ships' lamps—small lamps on my principle having shown a much more brilliant light than the larger lamps tried against them.

Take two lighthouse or pier-head lamps of the same size, and the one constructed under my new patent will give 20 or 30 times more light than is possible to be obtained from those in ordinary use, and which causes my light to be seen to advantage in hazy or foggy weather.

Another great advantage which a lighthouse or lamp constructed on my principle would possess would be the regulating the power of the light. For example, so much power is not required on a clear as on a hazy or foggy night—on the former occasion, only the upper and lower tiers of lenses need be lighted; on the latter occasion, all the tiers of which the lamp is constructed.

One of the new lighthouse lamps is, by order of the authorities of the Royal Yacht Squadron, about to be erected at Cowes.

J. W. D. B.

HALL'S PATENT RAILWAY BRAKE APPARATUS.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN:—In a report lately addressed by Captain Galton, R. E., to the Lords' Committee of Privy Council for Trade, on the Accidents which occurred on Railways in the year 1858, that experienced officer says:—"Safety from collisions would be very largely increased if the guard or the engine-driver of a train were enabled to apply brakes to a sufficient number of carriages to enable it to be stopped in 300 or 400 yards. The application of brakes to several of the vehicles of a train, instead of only one to a heavy brake van at one end, causes far less wear and tear to the rolling stock and the road." And again, in the same report, Captain Galton says, that a certain gentleman's brakes "are efficient, but not perfect," and that "they require to be adjusted periodically as the brake blocks wear away," adding, "the efficient action of a system of continuous brakes, no doubt, to some extent, depends upon the adoption of the system by all companies who interchange carriages or railways; but if the larger railway companies would adopt a system of continuous brakes for their own stock, the cases would be few where careful arrangements in making up the trains would not enable the system to be effectually applied."

From these observations I am undoubtedly at liberty to conclude (1.) That if the railway companies would adopt an efficient system of brakes, the public would, Captain Galton believes, derive a large increase of safety. (2.) That Captain Galton considers the following conditions essential to a perfect (and therefore an efficient) system of brakes, viz., (a) that the system shall be applicable to numerous carriages of a train; (b) that it shall not require adjustment because of the wear of the brake blocks; (c) that it shall be such as will afford no obstacle to the interchange of carriages among railway companies. In addition to these conditions, the able and gallant officer whom I have quoted would, of course, further require that the system should be moderate in cost, simple in construction, ready and certain in its action, and unattended by any large amount of labour or trouble.

Now, I am fully prepared to show to any railway director, manager, engineer, or other official person, that the system of railway brakes invented and patented by me in 1857, fairly and entirely fulfils all these conditions. In the first place it was designed expressly for application to any ordinary description of railway carriage, van, or truck, and its action is so immediate and powerful, that by its means a train of carriages may be stopped in a much shorter distance than 300 or 400 yards mentioned by Captain Galton. In the next place, the construction and arrangement of my apparatus is such, that it needs no adjustment whatever, however much the brake-blocks or frictional surfaces may wear. In the third place, my system is so devised, that carriages fitted with it may be interchanged, or turned round, in any or every conceivable manner without in any way offering an obstacle to the making up of a train. Lastly, my apparatus may unquestionably be cheaply fitted—is of a very simple character—acts with perfect readiness and certainty—and entails no considerable labour or trouble upon railway servants.

These statements will not, of course, be accepted as true without proof. But I make them with all confidence, and am willing to furnish the proof when it is asked for. Meantime, I desire to urge the consideration of this question upon those to whom the limbs and lives of the travelling public are committed. If Captain Galton be correct in this matter—and who can doubt that he is?—then the neglect of an invention which can accomplish all that I have said mine can effect, amounts to nothing less than the neglect of the public safety, and the wanton exposure of the public to peril.

I have here endeavoured to state the matter fairly; and although in the absence of all adverse criticism I speak confidently of the merits of my

apparatus, I believe I shall listen to such opinions as may be passed upon it, and such objections (if any) as may be brought against it, without prejudice or partiality. My sole objects are to draw the careful attention of railway officials to what I deem to be a life-saving invention, and to have it adopted if it be found all that I believe it to be. I would only say, in conclusion, that I consider I have now discharged my duty in connexion with this invention, and feel that I must henceforth leave those who are able to investigate it, and to adopt it, if it be really an efficient system, to do theirs.

This apparatus consists of a square sliding bar,* suspended under each carriage, the connexion being made by a universal joint coupling,† so as to render the break continuous throughout the train, thus making it possible to apply three or four brakes simultaneously. In making up a train, the brake-blocks of the brake-vans are screwed up close to the rims of the wheels, and then the coupling is effected so as to avoid the possibility of slack. The brake-blocks are so arranged on the carriages that two operate in each direction, so that the carriages may be moved either backwards or forwards indiscriminately; but this is not the case with those attached to the tenders and the break-van. There is a worm-wheel on the spindle of the handle from the van, working into a cog-wheel loose on the longitudinal shaft. On this shaft there is a screw working in a loose collar, to which are attached the ends of one pair of levers, working the arm of a lever, on a fixed shaft, also carrying the lever to which the blocks are attached.—(See Minutes of the Institution of Civil Engineers, 23rd November, 1858; *Mechanics' Magazine*, 24th April, 1858; *The Engineer*, 10th Dec., 1858.)

I am, gentlemen, yours obediently,

WALTER HALL.

Erith, 20th July, 1859.

ELECTRIC TELEGRAPH CABLES.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—Having received several letters from Mr. J. Hearder, of Plymouth, in reference to his patent for constructing telegraph cables, he therein attempts to lay claim to that which the public has a right, viz., the covering of copper wire with cotton or other fibre, previously to covering it with india-rubber or gutta-percha. We find in your journal of September the 4th, 1858, page 220, Mr. Hearder's specification of his patent. "First, he covers the conductor with cotton, silk, wool, hair, flax, or other porous substance or substances, in any of their forms, in one or more layers, previously to coating it with the insulating material, which may be india-rubber, gutta-percha, or any of their compounds, or any other insulating composition; or, secondly, he coats the wire with the insulating material." We are prepared to show that this has been done at least ten years ago for telegraphic purposes, and as a proof we have sent him a specimen. Mr. Hearder's specification further states that he "then applies any of the before-mentioned porous or fibrous substances over the insulating material; or, thirdly, coats the conductor with the fibrous, porous, or

* This longitudinal bar enters the square sockets of the universal joints, and is of such a length that when the train is extended to its greatest length, it will not be withdrawn from its sockets. Upon this bar is placed a shoulder, which is set fast by a set-screw, and on either side of this shoulder is placed a helical spring, which bears against the plates that support the longitudinal bar, and offers a certain amount of resistance to the motion of the bar in either direction. In the event of a concussion taking place upon the train or between the parts of the train, these springs will receive the shock gradually, and prevent, or aid in preventing injury to the train. By placing pins through the several bars or shafts within the universal joints, the said shafts and joints would act as couplings, and keep the carriages connected in the event of the ordinary connexions giving way. With this arrangement guard chains might be dispensed with.

† This coupling has two centre pins, which pass through the hollow centre-piece, so that when either of them is removed the joint becomes detached. This hollow centre-piece is a coupling to the apparatus, whenever the same is fixed to any part of the train, provided the universal joints are all of the same principle in the construction.

textile material in the manner described in the first process, and then applies the alternations of insulating and fibrous materials in the manner described in the second process." We give Mr. Hearder credit for this part of his invention, at the same time we believe, as practical men, the insulation would not remain perfect for any considerable length of time for deep sea cables; added to which he would find some serious difficulties to contend against in the manufacture of cables so constructed.

We cannot follow Mr. Hearder through such a multiplicity of ideas as to the construction of a cable under his patent, as it would be simply a waste of time. We find in page 221 the following ambiguous statement of carrying out his invention:—"In all cases I recommend the employment of a soft, adhesive, insulating medium, which shall adhere to the fibrous material as well as to the surface of the more solid insulating substance used for the several coatings, in order to prevent the layers from sliding over each other." We must confess that we are somewhat puzzled to understand how this part of his invention is to be accomplished, as Mr. Hearder does not explain. Does he mean wax of any sort? as we should very much like to know what he really intends to use, for we are quite sure he cannot carry out his invention if he is not in a position to state what the "soft insulating medium" is, so as to adhere to the "surface of the more solid insulating substance." Perhaps it would be better to state for Mr. Hearder's information, that gutta-percha will not adhere to india-rubber or cotton to the extent required for submarine cables; the reasons are obvious to those "practically acquainted" with the use of these gums. "I am aware," says Mr. Hearder, "that wire has been coated with fibrous or textile substances to effect the adhesion of the insulating materials, which would not adhere sufficiently to the wire without them." How could Mr. Hearder, upon making this admission, lay claim to it as his invention? We therefore repudiate such a monstrous claim, as to whether it would assist the insulation or otherwise.

We beg, therefore, to state on public grounds, that "no part" of Mr. Hearder's invention is essential in constructing cables under our patent; in fact, we see not the least advantage to be derived from it. We believe, as Mr. Hearder states, that gutta-percha is not the best insulator for submarine cables; we are also of opinion, if he had been in possession of the properties of "pure india-rubber" as an insulator, and had known the practical method of applying it for insulation, he would not have attempted to construct such a cable as his on "theory" apart from all the "mechanical difficulties" he would have to contend against. We are, Gentlemen,

Yours most obediently,

HALL AND WELLS.

Steam Mills, Mansfield-st., Borough-road,
18th July, 1859.

THE GREAT RAM.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—I take the liberty of leaving for your inspection a model of an elongated steel bolt, having two longitudinal wooden wings and a latitudinal wooden bolt passing through its diameter near the base, forming two well-defined "turons" on either side. The bolt is poised on these four wooden supporters, so that the body of the bolt cannot abrade on the interior of the rifle, whether rifled cannon or small arm. I should like to try an experiment with a well-tempered steel bolt, formed on this principle, against the iron sides of the great steam ram, when quite finished at a cost of £300,000; the experiment to be made from a long 68-pounder brass cannon, rifled with four grooves, the length of the bolt to be two and a half diameters of the base of the gun; the front face of the bolt to be slightly cupped, after the manner of a steel punch—this experiment being made when the ram is quite

finished, will be the more interesting to the public who pay the cost.

I remain, Gentlemen, your obedient servant,
J. NORTON.

NOTE.—Mr. Lancaster has shown me a new compound metal of the bronze nature, which is very tensile, not corrodible, and is therefore well adapted for rifle cannon.

Rosherville, 30th July, 1859.

Law Case.

COURT OF CHANCERY, Lincoln's-Inn, June 29.—
(Before Vice-Chancellor Sir J. Stuart.)

CLARK'S PATENT BOAT-LOWERING BLOCKS.

CLARK V. FERGUSON.

This was a motion for an injunction to restrain the defendants from manufacturing or selling any blocks made according to or in imitation of the mode described in the plaintiff's specification, and from infringing the plaintiff's letters patent, and from using the invention of the defendant, James Nash, without the leave and license of the plaintiff, and from proceeding with an application for the grant of letters patent to the defendant James Nash. The plaintiff's case was that in April last he had obtained letters patent for an improved safety block, to be used in lowering ships' boats and other analogous purposes, and that before filing his specification he had employed the defendants, Messrs. Ferguson, who were blockmakers at Millwall, to construct blocks for him according to his invention. In the progress of such manufacture the defendant, James Nash, who was the foreman of Messrs. Ferguson, invented an improvement on the plaintiff's invention, and the defendants thereupon proposed that such improvement should be introduced into the specification which was about to be filed, and that in consideration of such improvement they should be allowed a share of the profits to be derived from the plaintiff's patent. The plaintiff not having acceded to the defendants' proposal, he alleged that they thereupon threatened to manufacture blocks according to the alleged improved mode discovered by the defendant Nash, and thereupon he filed this bill, on the ground that Nash's block was only a colourable variation from his. The plaintiff's invention consists of a certain combination of mechanism, whereby, by means of an eccentric hook attached to the bottom of the lower blocks of a boat's tackle, the boat can be freed from the tackle by which it has been lowered immediately on touching the water.

Mr. Bacon and Mr. Freeling appeared in support of the motion.

Mr. Malins and Mr. Druce, for the defendants, said that they were willing to give an undertaking not to use the plaintiff's patent, or that the motion should stand over with liberty to the plaintiff to bring such action as he might be advised.

The Vice-Chancellor said this was not the ordinary case of the infringement of a patent, but the litigation arose in consequence of the plaintiff not having acceded to the defendants' proposal to embody in his specification Nash's improvement. It was in the discretion of the Court as to whether it would impose on a patentee the necessity of bringing an action to establish the validity of his patent, and he did not think that that was a case in which he should make any such terms; for it was only as an after thought, and after the plaintiff had declined to accede to the defendants' proposal, that the defendants called in question the plaintiff's invention. The plaintiff was entitled to an injunction restraining the defendants from manufacturing or selling any blocks made according to, or in imitation of, the mode described in the plaintiff's specification, and from infringing the plaintiff's letters patent; but there would be no order to prevent the defendants from using Nash's invention, or from applying to the Attorney-General for a patent for Nash's improvement.

Parliamentary Proceedings.

HOUSE OF COMMONS.

JULY 28, 1869.

TELEGRAPHIC CABLES.

Sir W. P. GALLWEY asked the Secretary to the Admiralty whether any and what experiments were proposed to be made as to laying telegraphic cables in deep water, before risking the sum voted for a cable to Gibraltar.

Lord C. PAGET replied that experiments were now in progress, under the superintendence of the Board of Trade, and under the control of those eminent engineers, Mr. Stephenson and Sir C. Bright, with the view of testing the composition of the outer coverings of telegraphic cables.

RIFLING OF CANNON.

Sir H. VERNY asked the Secretary of State for War whether any steps were being taken, and what, for the rifling of the smooth-bored iron cannon in store for the supply of the army, navy, and forts in the interval that must elapse before a sufficient number of Armstrong guns can be manufactured.

Mr. S. HERBERT said the Government had authorised experiments to be made in rifling the ordinary iron guns, and one gun would be tried next week. Similar orders would be given at the factory at Woolwich, and he hoped soon to see from 15 to 16 iron rifled guns produced per week.

COINAGE.

Leave was given to Mr. LAING to bring in a Bill to extend the enactments relating to the copper coin to coin of mixed metals.

The Bill was read a first time. It has since been carried forward through various stages.

JULY 29, 1869.

GAS IN BARRACKS.

Mr. BRADY asked the Secretary of State for War whether it was the intention of the Government to adopt gas in lieu of the present mode of lighting the military camp at Aldershot; and, if so, would the Government construct their own works.

Mr. S. HERBERT said it was the intention of the Government next year to introduce gas into barracks, and to construct works for that purpose, but they did not intend to introduce gas into the camp.

Proceedings of Societies.

INSTITUTION OF MECHANICAL ENGINEERS.

The general meeting of the members of this Institution was held on Wednesday, the 27th ult., at the house of the Institution, Newhall Street, Birmingham; Joseph Whitworth, Esq., Vice-President, in the chair. The Secretary (Mr. W. P. Marshall) read the minutes of the previous meeting, and several new members were elected. An abstract was read of a paper "ON THE CONSTRUCTION OF HOT-BLAST OVENS FOR IRON FURNACES," by Mr. Henry Marten, of Wolverhampton, the discussion of which was adjourned from the previous meeting.—Mr. Neilson gave an interesting account of the circumstances under which the idea of hot-blast first occurred to him, and his early experiments in the practical application of the plan to iron furnaces. If made from equally good materials the hot-blast iron was found to be as good, he said, as cold-blast, and some of the strongest castings had been obtained from judicious mixtures of hot-blast irons.—Other speakers expressed the same opinion, and commented upon a recent report by Government Commissioners upon the marine engines of the navy, in which it was proposed to exclude the use of hot-blast iron in their construction; and considered such a proposal was not based upon sufficient investigation of the subject, and was directly opposed to the results of general experience. The next paper was "ON THE APPLICATION OF THE DECIMAL SYSTEM OF MEASUREMENT TO MECHANICAL ENGINEERING WORK, &c.," by Mr. John Fernie, of Derby.

The following letter may deserve a line or two of space:—"Gentlemen,—I observe that my directors are inviting the inventive world to send in to them all the plans and designs ingenuity can suggest for laying me successfully in my ocean home. To this I have no objection, but I cannot help suggesting that it is only due to myself that, as in all other great competitions, some respectable premium should accompany the invitation, and be offered by my managers and directors whose right to speculate on the inventive ingenuity of the public I for one repudiate most sincerely, ATLANTIC CABLE."

Our Weekly Gossip.

A series of experiments is about to be conducted by Captain Galton on the part of the Board of Trade, Mr. R. Stephenson, M.P., and Professor Wheatstone, to determine the best description of cable for the proposed line of telegraph from Falmouth to Gibraltar. The experiments are to be carried on with the aid of the Atlantic Telegraph Company, and will comprise an investigation into the comparative value of gutta-percha and india-rubber, the best mode of insulation, and other questions connected with the manufacture of deep submarine lines.

The following are the main provisions of a Bill, prepared and brought in by Mr. Laing and Mr. Chancellor of the Exchequer, and now in progress through Parliament, "to extend the enactments relating to the copper coin to coin of mixed metal." When any coin of bronze or mixed metal shall be current by virtue of any Proclamation that may be issued by Her Majesty, all the penalties and provisions of the Act of the Session holden in the second and third years of King William the IV. "for consolidating and amending the laws relating to the coin," which are applicable to the current copper coin, or offences or acts relating thereto, shall be applicable to such current coin of bronze or mixed metal or the like offences or acts relating thereto; and sections twelve and fourteen of the said Act, and all other provisions of such Act, and all enactments whatever where current copper coin is mentioned, shall be construed and take effect as if in addition to copper coin, current coin of bronze, or mixed metal, had also been in any such case mentioned or referred to.

At the last meeting of the Institution of Mechanical Engineers at Birmingham, Mr. Whitworth exhibited his fine measuring machine, used for making standards of length, in which the bar to be measured is placed horizontally between the two end surfaces of the machine, a thin flat piece of iron called the gravity piece being introduced between the bar and the end screw of the machine; the screw is advanced and brought into contact with the gravity piece until the latter is only just able when raised to fall again; and by then advancing the screw only one-millionth of an inch further, the gravity-piece remains suspended between the two surfaces: thus one-millionth of an inch is rendered distinctly apparent, and standards of length are obtained by the machine with perfect correctness to the millionth of an inch by repeating the same process with corresponding bars. Mr. Whitworth also showed a set of standard plugs for the decimal wire gauges, and specimens of the gauges manufactured from these standards by Mr. Peter Stubs, of Warrington. Some of the decimal rules, twenty and thirty inches long, now in use in the workshop, were also exhibited, made by Mr. Sampson Aston, of Birmingham, from Mr. Whitworth's standard.

The editor of the *Athenaeum*, in his last number, says:—"A few days ago we saw the range and accuracy of the new Armstrong gun tested in a way which demands a note. Cooling ourselves on the Essex coast, near the artillery practising ground, we were asked to see the firing, and while this goes slowly and solemnly on one of them spies a flight of geese far out to sea. 'There, they light on yon sandbank.' Up go a dozen glasses. Yes; there they flicker in the sun, gray and white, mere specks in the blue sea air. Load the gun—load at the breach—poise—touch—bang! Boat off there to the sands! A signal tells the tale. The shot has struck the swarm—a life is taken from the flight—and this at six miles seven furlongs from the mouth of the gun! A shot as well aimed from Primrose-hill should hit the ball on Greenwich Observatory, or, if fired from Richmond Park, should bring down a rider in Rotten-row. Here is a fact worth the attention of those Austrian engineers who have just come to London to study our new artillery and learn how to defend Verona against the Frank." We confess we are "cynical" enough to disbelieve this curious statement as it stands. Isn't there a mistake as to the animal? Have we not here the hit of a *canard* rather than the hitting of a goose?

The impossibility of rendering a strong box altogether safe against theft by means of skeleton keys has led a locksmith in Frankfort-on-the-Main to hit upon the ingenious idea of constructing a strong box without any keyhole at all, and which even the owner himself cannot open. Why, what's the use of such a box? you will ask. But, observe, inside is a clockwork, the hand of which the owner places at the hour and minute when he again wants to have access to the box. The clockwork begins to move as soon as the lid is shut, and opens the lock from the inside at the moment which the hand indicates. Time, dependent

upon the owner, is the key to the lock—a key which can neither be stolen from him nor imitated.

Lieut. Col. G. W. H. Ross, of the Rifle Militia, writing from Jersey to the *Times* says:—"Having observed that the Duke of Somerset has stated in answer to Lord Lyndhurst that no authentic information has reached him of the employment of rifled cannon in the French navy, I beg to say that when I visited Cherbourg, in the month of March last, I saw a number of new rifled cannon (ships' guns) lying on the quay, close to the Arsenal. They were of the two grooved pattern, recently introduced by the Emperor into the French army."

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgement:—

STEAM ENGINES, &c., 2868, 2894, 2897.
BOILERS AND THEIR FURNACES. *None.*
ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 2869, 2893.
SHIPS AND BOATS, including their fittings, 2874, 2892.
CULTIVATION OF THE SOIL, including agricultural and horticultural implements and machines, 2875.
FOOD AND BEVERAGES, including apparatus for preparing food for men and animals. *None.*
FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 2873, 2887, 2899, 2904.
BUILDINGS AND BUILDING MATERIALS, including sewers, drain-pipes, brick and tile machines, &c. *None.*
LIGHTING, HEATING, AND VENTILATING, 2900.
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 2890, 2898, 2903.
METALS, including apparatus for their manufacture, 2879, 2881, 2883, 2895.
CHEMISTRY AND PHOTOGRAPHY. *None.*
ELECTRICAL APPARATUS, 2884, 2888, 2891.
WARFARE, 2871, 2885, 2896.
LETTER PRESS PRINTING &c. *None.*
MISCELLANEOUS, 2870, 2872, 2876, 2877, 2878, 2890, 2882, 2886, 2889, 2901, 2902, 2903, 2906.

2869. D. ROWAN. "Improvements in steam-engines." Dated Dec. 15, 1868.

In one arrangement provided by this invention, which may be called the "inverted duplex cylinder design," and which is suitable for driving a screw-propeller, an inverted cylinder is placed on a suitable framing directly over the shaft, and this cylinder has a similar one placed (by preference concentrically) within it, together constituting what is herein termed a duplex cylinder, which comprises a central cylindrical space surrounded by an annular space; pistons working in these two spaces are connected by their rods, which pass out through the bottom covers to one cross head, a connecting rod or rods passing thence to a crank on the shaft. The fresh steam from the boiler first enters the central cylinder, next passes thence to the opposite end of the annular cylinder, and finally passes from the annular cylinder to the condenser. A complete set of engines comprises two or more duplex cylinders connected to different cranks in the usual way. There are several modifications given in the specification of this invention, including an arrangement for operating the valves. *Patent completed.*

2869. H. BRIDGES. "Improvements in the means of working brakes on carriages on railways." Dated Dec. 15, 1868.

Here the inventor places under each carriage in a horizontal position, and extending the whole length of such carriage, a screw shaft having on the screw part thereof a wormed nut, connecting rods being attached at one end to the nut, and at the other to a lever or wheel. On the same shaft a toothed bevil wheel works into another toothed wheel on a vertical shaft, therefore when this vertical shaft is moved round, it will by the toothed bevil wheels cause the screw shaft to revolve, and the nut being restrained from revolving with the screw shaft, will traverse or move longitudinally along the screw shaft, and carry with it the connecting rods, and thereby actuate the brake against the rails. *Patent completed.*

2870. F. C. N. J. MIGNON. "Improvements in manufacturing screws, rivets, nails, spikes, and all similar articles made of metallic wire, and in the machines connected therewith." Dated Dec. 15, 1868.

This includes a whole set of new machines for performing the operations, which are four in number, and consist, 1, in heading or upsetting; 2, in turning the head; 3, in nicking the head; 4, in cutting the threads. Each of the above-mentioned is performed by a different machine, and there is also a feeding apparatus. *Patent completed.*

2871. A. V. NEWTON. "Improved machinery for manufacturing bullets." (A communication.) Dated Dec. 15, 1858.

This relates to an arrangement of machinery in which a punch and set of dies for pressing blanks or pieces of lead into a form approximating to that desired for the bullets, are combined within a revolving core, which serves, firstly, to produce a central cavity when that is required in the bullets, and secondly, as a mandril to revolve the bullet, for finishing their exteriors by the operation of turning. The invention also consists in the use of an automatically operating cutter in combination with the revolving core for turning the bullets. It also consists in the use in combination with the revolving core of a centre piece having an automatic operation for confining the bullets upon the revolving core during the turning operation, and afterwards releasing them and moving out of the way to permit the succeeding operations of the dies. *Patent completed.*

2872. A. V. NEWTON. "An improved arrangement of condensing apparatus." (A communication.) Dated Dec. 15, 1858.

This relates to a novel construction of condenser, in which a series of parallel vertical cells or flat tubes are used to receive the steam to be condensed. These cells or steam chambers are enclosed within a steam tight metallic cylinder casing, leaving between and around them a space for the circulation of water. At their upper part the chambers are connected by pipes with the exhaust steam supply pipe, and in like manner at their lower end with a pipe leading to an exhaust pump. The water of condensation is drawn from these chambers by this pump, and forced into the case surrounding the condensing chambers. This case or cylinder is connected at its upper part by pipes with the steam boilers. As, therefore, the condensed water thrown into the cylinder circulates round the condensing cells or chambers, it becomes heated by extracting the heat therefrom, and thence passes upwards to the boiler. *Patent completed.*

2873. J. BULLOUGH. "Improvements in looms." Dated Dec. 15, 1858.

The required motion is here given by any suitable number of healds for forming the shed according to the desired patterns by attaching them to cords passing over guide pulleys, which cords are connected to other cords, wires, or rods in a horizontal position having collars, knobs, or hooks upon them. At the top or other convenient part of the loom one or more rocking or oscillating shafts are worked for giving an oscillating motion or sliding movement to one or more bars, plates, or knives, so that when the horizontal cards, wires, or rods are pressed on their tops by pegs on a pattern cylinder or lattice, the knobs or hooks shall either be put on or taken off the bar or bars, and thereby raise the healds or leave them free according to the bond of the hooks. *Patent completed.*

2874. C. F. VASSEROT. "An improved pendulum governor for regulating the supply of steam to the cylinders of marine engines." (A communication.) Dated Dec. 15, 1858.

This consists of a pendulum, which, by means of a guide and rollers, vibrates only in a plane, parallel and coincident with that of the axis of the ship. By means of one or more arms, the pendulum is connected with a vertical spindle, which has a screw tapped on its upper end. Upon the screw is placed a muff, having a small fly-wheel attached to it, and which is kept from moving upwards by a ring placed above it, and held by a set screw. Attached to the muff, by a strap and pins, and stretching in a direction at right angles to the last-mentioned screw spindle, is another spindle or arm having its extremities made of a forked or gimbal form, and having cut on its centre a right and left handed thread over which a union or junction having similar threads cut upon it works, so that by turning the union to the right or left this spindle is lengthened or shortened. The other extremity of this forked spindle is attached to a muff similar in every respect to the first described one, and mounted upon another spindle or rod, having its one extremity formed as a screw, the other attached to and vibrating with the axle of the throttle valve of the steam pipe. *Patent completed.*

2875. W. CLARK. "Improved agricultural implements." (A communication.) Dated Dec. 15, 1858.

This relates to farming implements, having for their object to open up and stir and break up the sub-soil after the passage of a plough through the

ground without mixing the earth of the subsoil with the upper layer of arable ground. A hopper placed in front of the implement permits of a certain quantity of lime being dropped into the furrow of the plough to be mixed with the subsoil. *Patent completed.*

2876. J. WARDILL. "An improved stopper or controller, to stop and control the running out of chains and ropes." Dated Dec. 15, 1858.

This consists in constructing a stopper or controller with hinged jaws, one being hinged to each side of a bed along which the chain or rope runs, and which jaws, by means of a screw lever or other suitable power applied at or near the upper part thereof are made to press down upon, grip, and entirely or partially stop the passage of the chain or rope. *Patent completed.*

2877. G. BELL. "An improvement in matches and fuses." Dated Dec. 15, 1858.

This consists in the use of a metal shaft which is dipped in any igniting composition suitable to the purpose for which the match or fusee is intended. The composition will be found to burn upon and adhere while burning to the metal shaft. *Patent abandoned.*

2878. T. MOSE. "Improvements in printing bank notes, bills of exchange, and other documents, requiring like security against being copied." Dated Dec. 15, 1858.

Here the paper on which a bank note, &c., is to be printed is coated with colouring matter. The colours preferred are yellow, red, brown, or green, and the colours are so prepared that they cannot be removed by any chemical agency unless the paper be destroyed. Burnt clay or carbon is used in compounding the colours, and they are mixed with drying oils or varnishes and are applied by blocks or otherwise. *Patent completed.*

2879. W. MORGAN. "Improvements in the manufacture of iron." Dated Dec. 15, 1858.

This relates to the smelting iron ores in which the quantity of alumina present is equal to or exceeds one-half the quantity of silica, and the invention consists in employing as a flux in the blast furnace when smelting such ores sandstone, sand, or other matter containing silica in a comparatively pure form, that is to say, at least 75 per cent. of that substance. *Patent completed.*

2880. R. and R. WILSON. "Certain improvements in the preparation of leather in combination with india-rubber and other materials, for the manufacturing of hose-pipes, and other purposes where leather is required to be impervious to water, steam, or frost." Dated December 16, 1858.

Here the inventors take leather of suitable thickness and strength for hose pipes and for other purposes where the article is required to be impervious to or to resist action of steam, hot-water, or frost, and first thoroughly cleanse the same by scouring in cold water; the inner surface is then shaved evenly to the thickness required and a layer of dubbing composed of oil and tallow is applied to it, and it is hung up until the dubbing is well absorbed. The outer grain of the leather is then taken off with a currier's knife, and the leather is punctured by a roller the surface of which is set with small spikes or teeth. A solution of india-rubber combined with shellac is then applied to the surface of the leather, which enters into and is retained by the small punctures and grain of the leather. A thin layer of india-rubber solution is then applied, which serves as a foundation to receive a covering of vulcanized india-rubber cloth. The combined sheets of leather and india-rubber are then stretched upon a drum so as to cause the india-rubber to adhere firmly to the leather, and when this is accomplished the outer surface of the leather (previously punctured) has a coating of the india-rubber solution applied thereto. *Patent completed.*

2881. W. H. CARMONT and W. CORBETT. "An improved mode of constructing furnaces for the production of wrought-iron and steel, and manufacturing such metals into ingots and other forms." Dated Dec. 16, 1858.

Here the flues are so constructed as to rise perpendicularly from the grate, thereby carrying off all the deleterious gases generated, and preventing such gases coming in contact or becoming incorporated with the metals so manufactured. The heat is also caused powerfully to reflect and reverberate upon the metals, at the same time preventing all flame or smoke passing over or coming in contact with the metals whilst in a heated or smelting state. *Patent abandoned.*

2882. A. and J. STOKES. "New or improved machinery for the manufacture of screws." Dated Dec. 16, 1858.

Here the machinery effects the opening and closing

of the dies or cutters by which the worming and turning of the screw is effected, and also throws the lathe out of gear with the driving power without the intervention of an attendant. *Patent completed.*

2883. R. MURPHY. "A new or improved manufacture of cast steel." Dated Dec. 16, 1858.

This consists in manufacturing cast steel from cast iron which has been wholly or nearly decarburized by passing air through it while it is in a molten state, the conversion of the iron into cast steel being effected by melting the same and treating it whilst melting or when melted with a triple compound or mixture consisting of or containing iron carbon and manganese. *Patent completed.*

2884. J. H. SELWYN. "A novel apparatus for paying out or laying down submarine telegraph cables or wires, and for raising the same after they have been laid down." Dated Dec. 16, 1858.

This invention is described at pages 123 and 155 of the MECHANICS' MAGAZINE (new series). *Patent completed.*

2885. J. W. EDGE. "A certain improvement in balls, bullets, or other projectiles to be employed in fire-arms or ordnance." Dated Dec. 16, 1858.

Here the projectile is of that description which is partially hollow, and the invention consists in filling such cavity with a composition of wax and tallow, and in so perforating the sides of the projectile that upon the explosion of the powder such lubricating material may be forced through the apertures and effect the lubrication of the barrel. *Patent completed.*

2886. J. W. FRIEND. "Improved apparatus for ascertaining and registering the depth and flow of liquids and the distances run by ships at sea." Dated Dec. 16, 1858.

This consists in enclosing within an outer case tangent tooth and pinion gear in connection with a fan or paddle wheel by which the resistance caused by the water impinging upon the floats or paddles may be correctly ascertained, and corresponding results registered by graduated wheel plates or dials presenting the numeral or scale corresponding to the said resistance. For ascertaining the depth of water at sea, the speed or distance run by vessels, or the amount of fluid otherwise passed through the apparatus, the said apparatus when employed for ascertaining the distance run by vessels being provided with metallic wings or blades presented obliquely to the water, by which the instrument is kept constantly submerged, and when used for registering the flow of liquids furnished with concentric slot openings formed eccentrically in the channel in which the fan or paddle wheel revolves, through the medium of which the water, &c., is directed against the floats or paddles. *Patent completed.*

2887. A. MACKENZIE. "Improvements in sewing machines." Dated Dec. 16, 1858.

Here, according to one portion of the invention, the circular needle machine is referred to, the sewing or stitching action being effected by the combined action of a straight needle of vertical action, and a curved needle of horizontal action. The framing of the machine is generally similar to that already in use, consisting of a rectangular table frame, open beneath, and formed with a platform top for the working operation. *Patent abandoned.*

2888. J. J. MARCAIS. "Improvements in galvanic batteries." Dated Dec. 16, 1858.

This invention is not described apart from the drawings. *Patent completed.*

2889. W. WHITE and J. PARLEY. "Improvements in the preparation or treatment of 'carton pierre,' and such like composition, and in the application thereof to the coating or covering of walls and other surfaces." Dated Dec. 16, 1858.

This relates in mixing with "carton pierre," &c., material adapted to resist moisture, such as pitch, tar, rosin, gutta-percha, india-rubber, or resinous or bituminous substances of a like nature, or of cement in powder used with the "carton pierre," either alone or in combination with the above-named materials. It also relates to the application of such matters as a covering for surfaces and partitions of buildings, &c. *Patent abandoned.*

2890. R. A. BROOMAN. "An improvement in plating and gilding forks, spoons, and other metal articles." (A communication.) Dated Dec. 16, 1858.

This consists in plating those portions of the forks, spoons, &c., which are subjected to more wear than others, such as the prongs of forks and the bowls of spoons, with a thicker coating than the other portions. The patentee takes any article which has been uniformly coated by the aid of the galvanic bath, and heats it, and by affinity of metal for metal solders on to those parts requiring a thicker coating as many layers of leaf silver or gold as may be necessary to produce the desired thickness. *Patent completed.*

2891. W. CLARK. "Improvements in submarine electric telegraph cables or conductors." (A communication.) Dated Dec. 18, 1858.

Round a cord of elastic material, which may be either a conductor or non-conductor, the inventor winds a copper wire, for example, in contiguous spirals, as in covered springs for musical instruments, &c.; over this he again winds another wire of about the same diameter, so that this second helix falls in the furrows of the first. He obtains thus a conductor composed of an elastic cord placed in the centre of two spiral superposed coils in which the spirals are wound so as to insure contact whatever may be the extension they suffer; for in proportion as the elastic core stretches, the exterior pressure causes the external spirals to bear on the spirals of the inner helix and forces them in the intervals of the spirals of the inner helix. *Patent completed.*

2892. J. J. ASTON. "Improvements in machinery or propellers applicable for the propulsion of ships, boats and other vessels on and through the water, and in the propelling of all such vessels on and through the water by means of such propellers." Dated Dec. 17, 1858.

These propellers consist of solid circular discs or rollers mounted on a central axis, and made of wood, metal, or wood and metal combined. They are flat at the sides, and have no floats, paddles, or projections on their plane peripheries. *Patent completed.*

2893. W. J. JOHNSON. "Improvements in machinery or apparatus for preparing for joining the rails of railways." Dated Dec. 17, 1858.

This relates, 1, to a method of cutting the rails so as to obtain correct lengths. For this purpose the inventor employs a portable apparatus constructed with a cutting tool to which a reciprocating motion is imparted. This tool is caused to reciprocate by an eccentric, and the traverse for the cut is gained by suspending the tool upon a centre, in which it is caused to swing. It relates, 2, to apparatus for making fish joints, and consists in combining the above described cutting apparatus with a drill or drills, so that the two operations may proceed simultaneously. It also consists in using a combination of two or more drills without the cutting tool, so that the like number of holes may be drilled at the same time. *Patent completed.*

2894. J. and J. INSHAW. "An improvement or improvements in locomotive engines." Dated Dec. 17, 1858.

Here the inventors place a friction wheel between the driving and leading wheels, and another friction wheel between the driving and trailing wheels, the said friction wheels being so situated that by a slight motion of their bearings they may be brought upon the peripheries of the driving and leading wheels and the driving and trailing wheels respectively of the locomotive. The leading wheels or trailing wheels or both are thus geared to the driving wheel, and receiving motion therefrom, facilitate the advance of the locomotive by their adhesion to the rails. The friction wheels may be brought into contact with the driving and leading wheels and trailing wheels, either by the action of a piston rod that is worked by a steam cylinder or otherwise. *Patent abandoned.*

2895. A. HINDE. "Improvements in treating or preparing the cinder or slag from puddling furnaces for the purpose of facilitating the manufacture of iron therefrom." Dated December 17, 1858.

This consists, 1, in calcining puddling furnace cinder, or slag, when used for the smelting of pig or cast-iron by performing the process in kilns built with flues, or external fire-places, similar in construction to those now used for the production of what is technically known in iron forges as "bull-dog," and in using the puddling furnace cinder or slag when so calcined in the blast furnace for the production of pig or cast-iron. It consists, 2, in mixing with puddling furnace cinder or slag previously to calcination, lime or limestone, and calcining the same in admixture with the cinder for purifying the said cinder, or assisting the subsequent process of smelting in the blast furnace. *Patent abandoned.*

2896. J. KERR. "Improvements in the construction of revolving fire-arms." Dated December 17, 1858.

Here the inventor is enabled to apply the ordinary gun-lock and cock with the usual safety bolt to revolving fire-arms. The lock is pulled off by the trigger blade in the usual manner, but by having an extra "bent" in the tumbler the lock can be snapped and cocked by simply pulling the trigger, for which purpose the inventor uses in conjunction with the extra bent above referred to a short lever in the trigger, which is kept in the proper position by a hook formed on its edge, and a stud on the top of the tumbler. The chamber is rotated in the ordinary way. It revolves on a rod or spindle inserted into its place

from behind, or from the front, and is adjusted or tightened up when necessary by an adjusting tube or nut, tapped into the base of the cylinder. The lever rod has no working fulcrum of its own, but it is curved at the heel, and such curved portion works between two fixed stud pins so that a moving axis is obtained, which axis is the point of junction with the plunger; by this arrangement no pins or slots are required in the lever. *Patent completed.*

2897. J. CLEGG. "Improvements in lubricating the valves and pistons of steam-engines." Dated December 17, 1858.

Here the lubricating apparatus is so formed that the oil, &c., is placed in a cup or vessel fixed above the steam-pipe leading from the steam boiler to the cylinder of the engine. Below the cup or vessel into which the oil, &c., is placed there is a cock, when the plug of which is turned the oil, &c., will pass downwards towards a vessel of a spherical or other form, at the upper part of which vessel a valve is applied which closes the passage into the vessel when pressed upwards by steam in the vessel. At the lower part of the vessel a valve is applied which opens upwards when pressed on by the steam below. The spherical or other formed vessel is connected to the steam-pipe by a tube on which there is a cock, so that when the plug thereof is turned the oil, &c., will flow out of the spherical vessel into the steam-pipe, and be carried onward by the steam to the valve or valves of the engine, and to the piston working on the steam-cylinder. *Patent completed.*

2898. J. KETCHUM. "Improvements in the method of roasting meat, poultry, game, by basting the same, and in the method of manufacturing the necessary apparatus for so doing." Dated December 18, 1858.

This consists of a perforated vessel which is to be suspended below the bottle-jack, or other roasting contrivance by hook, eye, or spindle. which hook, eye, or spindle projects above the said vessel so that it may hang steady, and the vessel being supplied with grease it will pass through the perforations and fall on the joint, &c., being roasted. The invention also includes an arrangement for raising the fat, &c., from a lower level into the aforesaid baster. *Patent completed.*

2899. J. AITKEN and J. BROOKS. "Improvements in looms." Dated December 18, 1858.

Here the inventors employ a moving "back bearing rail" and give it motion by attaching to it one or more arms, each furnished with a block of wood, which blocks are in a line with one or both of the connecting links from the cranks to the sword-arms, so that as the links move up and down in their to and fro movement either one or both come in contact at certain intervals with the block or blocks, thus causing the rail to vibrate so as to maintain an equal tension of the yarn beam and consequent strain upon the yarn. Or they produce the same effect by placing on the crank shaft an irregularly-shaped cam or tappet which comes in contact with an arm or arms fixed to the "back bearing rail," thereby causing the latter to vibrate at the exact time required. In connection with the aforesaid movements they employ a stationary rod fixed across the loom for holding the yarn in the same relative position with respect to the moving "back bearing rail" and yarn beam. They employ at the back of each shuttle box a coiled spring to which is attached a strap, so placed as to receive the picker gently when throwing the shuttle. Each strap may be readily adjusted as required, and in connection with the spring forms a yielding check of great efficiency. They employ an elastic break by attaching leather, &c., to an arm or lever of sufficient strength, but capable of slightly yielding so as to temper the shock when the break acts, and also its mode of adaptation. For working the stop rod they employ an elastic swell, consisting of a spring of the same form as the present swell, thus lessening the difficulty of communicating motion to the top rod, and preventing the excessive strain upon the fingers and chisel in the event of trapping the shuttle and also diminishing the wear of the shuttles. *Patent completed.*

2900. J. MACKENZIE. "Improvements in those gas burners known as ventilating sun burners." Dated Dec. 18, 1858.

This relates to an improvement in ventilating gas burners, known as "sun" burners. These burners consist of a number of jets placed horizontally under funnels, or inverted cones, or chimneys of sheet iron, &c., and this invention consists in perforating or forming apertures in part of the inner funnel, pipe, or chimney, and also in part of the outer one, in order to allow the light to pass, and in filling up the openings with talc, mica, or other suitable transparent material. The shadow on the walls will thereby be pre-

vented, and all parts of the ceiling will be equally lighted. *Patent completed.*

2901. A. MITCHELL. "Improved apparatus for registering the speed of engines and other machinery." Dated Dec. 18, 1858.

The object proposed to be effected here, in the case of an engine, for example, is the noting with a style or other marking instrument, upon suitably prepared paper, the number of strokes which it has made in a given time, using for this purpose the motive power derived from a clock or time-keeper, in combination with motive power derived from the engine whose performance it is desired to record. The way in which this combination of motive agency is to be applied may be varied—that is to say, the prepared paper may be carried under the style or marker by power derived from the engine, and the style or marker operated by the time-keeper, or vice versa. *Patent completed.*

2902. J. TAYLOR. "Improvements in the construction of pumps or engines for lifting and discharging water." Dated Dec. 18, 1858.

This consists in the suction and discharge valves being combined within the same valve chest by two intersecting divisions or partitions through which the openings or passages are made between the suction and the discharge; these openings are covered by preference with flap valves which lie at a suitable angle, or are held against the respective faces of the partition or divisional plates within the valve chest. The pumps may be single or double-acting barrels, and if two are used one should be placed on each side of the valve chest, and the suction and discharge openings or ways are common to both sets of valves; and the top and bottom parts of each barrel, in a double-action pump, would be connected with the same side of the suction chamber in the valve chest; and the air vessel should be placed above the valve chest, and may be so cast as to form the standard of the pump, or it may be attached to the valve chest. *Patent completed.*

2903. A. P. HOW. "Improvements in cocks or stop valves." Dated Dec. 18, 1858.

This consists in substituting for the ordinary plug-cock and the single station valve, a double bottom spindle valve (somewhat similar to the double beat valve) and in so constructing the shell of the cock or valve case as to form the two valve seats therein, and the inlet and outlet passages by covering the shell casting. *Patent abandoned.*

2904. E. WEBER. "Improvements in dyeing or colouring textile fabrics and materials, and in the machinery or apparatus connected therewith." Dated Dec. 13, 1858.

This relates to a former patent, and consists in constructing the vessel into which the materials to be dyed are contained of a larger diameter as compared to its depth than that described in the specification of the former patent, by which means the height of the layer or column of material contained between the disc and false bottom through which the dye liquid is to be forced is greatly reduced, and consequently a more uniform tint is obtained, whilst a considerable reduction in the power required to work the force pumps is effected. *Patent completed.*

2905. J. SOUTHER. "Improvements in apparatus for drying or airing linen, or other articles of wearing apparel." Dated Dec. 18, 1858.

Here the linen airer consists, under one modification, of two plain or turned bars of wood disposed horizontally and connected by two horizontal bars, cut to the length the linen airer is desired. The two end bars are raised from the floor by knobs or feet. In each of the end bars two uprights are arranged parallel to each other; these uprights are connected longitudinally by cross rails made either plain or ornamental—these longitudinal rails serve as supports by placing linen thereon. Other supporting rails are obtained by securing to each pair of uprights a horizontal bar which extends outwards. Beyond the upper longitudinal rails short vertical pieces are connected to the extremities of the horizontal bars. These vertical pieces have fitted to them cross rails which form supporting bars, parallel with, but lower than, the upper longitudinal rails before described. *Patent completed.*

2906. J. H. JOHNSON. "Improvements in apparatus for re-working the waste steam of steam-engines." (A communication.) Dated Dec. 18, 1858.

The steam having operated in the cylinders is conducted by a pipe to a close vessel, in which it is allowed to expand and lose a great portion of its original pressure. From this vessel it passes to a surface condenser, which may be composed of a number of tubes surrounded with cold water tubes, and within which tubes the steam passes and is condensed, when it is removed by a lift and force pump, and supplied through a coil of pipes in one of the furnaces to the boiler. By this means the steam is

regenerated and its temperature is raised considerably before entering the boiler. The condenser is contained in a water tank, which receives the injection water, such water being heated by the steam, and used partially for supplying the trifling feed required to the boiler. To prevent the heating of the pump packing it is proposed to keep such packing moistened by a jet of water supplied from a small tank on the upper part of the pump. *Patent abandoned.*

PROVISIONAL PROTECTIONS.

Dated June 21, 1859.

1405. W. C. Fuller. Improvements in india-rubber shackles, and in springs for carriages, and the metal fittings connected therewith.

Dated June 23, 1859.

1512. G. C. Grimes. Improvements in cigar or such like lights, and in the means of producing them.

Dated June 29, 1859.

1546. T. Wight. Improvements in the apparatus used in the manufacture of cast metal pipes and castings, termed core bars or spindles and chaplets.

Dated July 5, 1859.

1595. C. Barlow. Improvements in capstans. A communication.

1596. A. Beaulieu. Improvements in crinolines, and in machinery for manufacturing springs for such and other purposes. A communication.

Dated July 6, 1859.

1604. C. Hagan. Improvements in apparatus for curing smoky chimneys, and preventing down draught.

1605. S. Lloyd. Improvements in the manufacture of cast steel tyres.

Dated July 7, 1859.

1616. J. Smith. Improvements in propelling ships and other vessels.

Dated July 8, 1859.

1634. W. N. Nicholson. Improvements in machines for making and collecting hay, and for cutting thistles and weeds, which improvements in whole or in part are applicable to other agricultural implements where teeth or tines are used.

Dated July 9, 1859.

1640. W. MacKean. Improvements in the manufacture or treatment of farinaceous matters for the obtainment of starch and food.

Dated July 12, 1859.

1651. J. Luis. Imitation leather. A communication.

1655. G. White. Improvements in apparatus for counteracting the effects of collisions in railway trains.

Dated July 13, 1859.

1657. C. S. Walker and R. Hoyle. Improvements in machinery or apparatus for promoting the consumption of smoke in steam-boiler and other furnaces, and for preventing the explosion of steam-boilers.

1658. A. Cooper. Improvements in the manufacture of the grips of swords, and sword bayonets.

1659. J. S. Thomson. Improvements in steam-engines. A communication.

1660. W. Cotton. Improvements in means or apparatus for connecting together or uniting looped fabrics.

1661. J. Combe. Improvements in machinery for hacking flax and other fibrous substances.

1662. J. Taylor. Improvements in stoves and fire places, and in the arrangement of flues connected therewith.

Dated July 14, 1859.

1663. W. Walker. Improvements in the manufacture of metallic packages, and in machinery for manufacturing the same. A communication.

1664. R. Mushet. Improvements in the manufacture of shot and shell and other projectiles.

1665. R. Mushet. A new or improved manufacture of certain metallic compounds or alloys.

1666. J. Atkinson. Improvements in fire-arms.

1667. J. H. Johnson. Improvements in the manufacture of artificial fuel. A communication.

1668. J. Morgan. Improvements in apparatus for making candles.

1669. J. Bailey. Improvements in machinery or apparatus for stretching woven fabrics.

1670. R. Longstaff and A. Pullan. Improvements in traction or locomotive engines.

Dated July 15, 1859.

1671. C. Kingsford. Improvements in the preparation of peat and charcoal for fuel, in the manufacture of coke therefrom, and in the machinery and apparatus employed for effecting the same.

1672. W. Clark and W. Williams. Improvements in finishing woven fabrics.

1673. F. Brown. The preparation and manufacture of a new fibrous pulp for making paper, and for other useful purposes.

1674. R. Mushet. New or improved methods of manufacturing a certain metallic compound or alloy.

1675. H. G. de Chateaufort. An improved coverlet, called saphyr-cider-down coverlet.

1676. J. P. Farrar. Improvements in the treatment of iron.

1677. W. McAndrew and C. W. Boyd. Improvements in treating poppies, to obtain a product resembling opium therefrom.

1678. W. O. Carter. Improvements in machinery for sawing slate.

1679. F. Prince. An improvement in breech-loading fire-arms.

Dated July 16, 1859.

1680. J. Musgrave, jun. Improvements in the construction of steam-boilers.

1681. J. Bernard. Improvements in the construction and arrangement of hydraulic and other pumps, for forcing liquids and for obtaining pressure.

1682. C. Pottinger. Improvements in machinery or apparatus for dredging or excavating, and for driving piles.

1683. H. Cunnew. Improvements in elastic bands.

1684. P. A. A. Troutet. A new moveable stopper for gaseous liquids.

1685. W. M. Smith. The construction of fare-boxes for the prevention of fraud on the part of drivers, conductors, &c. A communication.

1686. M. H. Chapin. Improvements in the manufacture of gallons, tapes, or ribbons for supporting steel or other hoops used for distending ladies' dresses.

1687. T. Carliell. Improvements in vent pegs.

Dated July 18, 1859.

1691. J. Bernard. Improvements in the manufacture of boots and shoes, and the means employed therein.

1692. H. C. M. Cramer. Improvements in bedsteads.

1693. J. Shaw. Improvements in the manufacture of artificial fuel.

1694. A. Phillips. Improvements in weaving carpets and in the machinery or apparatus to be used therein, parts of which machinery or apparatus are applicable to the weaving of other fabrics.

1695. W. H. Hartfield. Improvements in apparatus employed in getting ships' anchors and in shackling chains.

1696. W. E. Newton. Improvements in the method of constructing and operating batteries for generating or exciting, by chemical action, electricity for telegraphic purposes. A communication.

1697. A. V. Newton. Improvements in the manufacture of india-rubber and other like fabrics. A communication.

Dated July 19, 1859.

1699. F. C. Bakewell. Improvements in extracting oils from coal and other minerals. A communication.

1700. J. Shanks. Improvements in mowing machines.

1701. H. Parent. Improvements in, or applicable to, looms for weaving.

Dated July 20, 1859.

1703. J. Erskine. Improvements in breech-loading fire-arms.

1705. W. E. Gedge. Improved apparatus for the prevention of accidents in mines, to be called a mining parachute. A communication.

1707. Earl of Caithness. Improvements in the permanent way of railways.

1709. W. E. Newton. Improvements in self-acting lithographic printing machines. A communication.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

(From the London Gazette, Aug. 2, 1859.)

684. W. B. Taylor. Looms.

714. J. Bickerton. Window sashes.

720. S. Newington. Distributing seeds.

724. W. P. Wilkins. Valves.

735. S. Oram. Superheating steam.

736. W. Adamson. Propelling vessels.

738. W. Middlebush. Propelling vessels.

740. F. Tillett. Cutting splints.

748. W. E. Wiley. Cases for needles, &c.

750. F. E. Sharp. Corking bottles.

762. W. Redgrave. Travelling cap.

763. E. Steane. Preventing candles dropping.

772. C. J. Richardson. Chimneys and flues.

774. J. Buckingham. Drawing fibres.

785. R. Searle. Telegraphs.

786. I. Spight. Horse hoes.

787. T. Taylor. Paper.

788. H. P. Burt. Preparing timber.

795. T. D. Shipman. Stamping. Partly a communication.

798. C. P. Coles. Defending guns and gunners.

805. T. Ivory. Rotary engines.

806. T. Ivory. Boilers and furnaces.

807. A. Morton. Sextants or quadrants.

813. D. K. Clark. Heating apparatus.

814. F. P. A. Aubertin. Food for animals.

824. A. Ripley and J. Roberts. Scraping leather.

861. J. A. H. Ballande. Paper and ink.

883. W. Henderson. Treating ores.

942. W. Sinnock. Telegraph cables.

956. W. Clark. Separating metals from their ores. A communication.

1099. W. Gossage. Alkaline silicates.

1101. W. Gossage. Caustic soda.

1329. W. Gossage. Iron and steel.

1512. G. C. Grimes. Cigar lights.

1527. W. E. Newton. Exhibiting stereoscopic pictures. A communication.

1592. A. V. Newton. Separating metals from their ores. A communication.

1597. W. E. Newton. Moving metals. A communication.

1640. W. MacKean. Starch and food.

1647. W. E. Newton. Magneto-electric machines. A communication.

1687. W. M. Smith. Fare-boxes. A communication.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed July 29, 1859.

283. S. B. Eveleigh.	357. A. Clark.
284. R. Needham.	427. R. Cookson and C. W. Homer.
290. G. A. Waller.	489. A. W. Smethurst.
296. E. E. Allen.	745. P. P. Boll and H. Reger.
304. J. Hirst, jun. and J. Hollingworth.	1317. B. Samuelson.
305. G. Leach.	

Sealed August 2, 1859.

309. W. Clayton and J. Goodfellow.	393. G. Hadwen and J. Wadsworth.
311. J. Petrie, jun., and T. Wrigley.	398. S. H. Huntly.
317. A. Allan.	418. R. Mushet.
320. R. A. Brooman.	443. H. Y. D. Scott.
322. G. H. Baylis and F. Robinson.	445. P. E. Fraissinet.
323. F. H. Maberly.	449. J. H. Johnson.
332. N. Greenhalgh, W. Shaw, & J. Mallison, jun.	458. P. A. J. Dujardin.
335. T. and B. C. Sykes.	596. P. E. Aimont.
347. J. Wilson.	1143. W. S. Booth.
	1431. W. Brown, jun., and S. Bathgate.

PATENTS ON WHICH THE THIRD YEAR'S STAMP DUTY HAS BEEN PAID.

1800. W. E. Newton.	1823. E. P. Chevalier.
1820. W. Wood and M. Smith.	2060. W. Moberly.
1821. W. Wood and M. Smith.	2121. J. B. Robinson.

NOTE.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office.

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, AUGUST 12, 1859.

THE GREATEST SHIP.

HAVING twice in one week visited the greatest ship that ever swam—having wondered at her from without and wearied over her within—having examined, once more, her structure, gone over her ponderous engines, seen their massive forms in motion, marked their wondrous ease of working—having exhausted, in short, all our powers both of inquiry and admiration upon this last and greatest wonder of the world, we really feel it difficult to address our readers worthily upon so great a subject.

Our first business, however, appears to be to point out with as much exactness as is possible to whom the merit of constructing this marvellous ship is due. This is unquestionably of prime importance, because, as Lord Stanley said on Monday, if the Great Eastern succeeds, she will be a greater step—indeed, apart from the contingencies of future experience, she is already a greater step—in the art of ship-building than has ever before been accomplished in one generation “from the day when man first began to traverse the sea.” It is impossible to look upon this ship, and to think of the promise which in a mercantile sense she holds out to us—of the enormous power of military transport with which she furnishes us—and of the services which even as a ship of war she is capable of rendering us—it is impossible, we say, to think, however imperfectly, of these things, and not at the same time to see that we probably owe far more to the man or men by whom she has been produced than to the greatest soldier, or seaman, or statesman alive. A man cannot open his eyes and look abroad over the modern world without seeing that the truly great men, the veritable heroes of this age, are they who clearly conceive and laboriously execute undertakings of this kind. In old times, when as a nation we had to fight incessantly for mere life, it was right enough to value our best fighting men above all others—to adorn them with titles and coronets—and to cluster them about the throne of our monarch. But fighting men are our greatest men no longer. The great ship-builder, the great engineer, the great merchant, these are the foremost leaders of this time, although we have not yet begun to call them dukes and earls, and to lift them to the fellowship of our sovereigns. To say the least, such men are inferior to no others. It is well worth while, then, to inquire to whom we owe the Great Eastern.

Fortunately for ourselves and for the future historian, the authorship, so to speak, of this vessel is pretty accurately defined. In so far as the mechanical design and construction of her are concerned—and these are all with which we have to do—Mr. Brunel and Mr. Scott Russell are the only two gentlemen who make any claim to the merit of it. Nor is it difficult to define with great accuracy how much of the merit is due to each of these gentlemen respectively. The statement made by Mr. Russell in his speech on board the ship on Monday last was conceived in so fair a spirit, and agrees so exactly with statements which Mr. Brunel has on former occasions made or sanctioned, that we cannot do better than repeat it here. It was part of his (Mr. Russell's) understanding with Mr. Brunel, he tells us, that the original conception of a large steam-ship to carry her own coal upon the longest voyage, so as to avoid all the waste of time and expense which was then

standing in the way of the prosperity of steam navigation for long distances, was absolutely and entirely Mr. Brunel's, and not his in the smallest degree. It was true that very soon after the thought struck Mr. Brunel, he came to him and said, “Now, I am not a shipbuilder, and I am not an engine-builder, and I come to you to see if you will devote your mind and attention to the carrying out of this problem to a successful issue. You and I will go together through the whole undertaking, *pari passu*, you shall design the ship according to your own lines, make the engines upon your own plan, and construct the ship according to the best of your experience and knowledge, but we shall always agree in this—that I am the father of the undertaking, and that I had the original conception.” To this Mr. Russell agreed, and to this he on Monday last gracefully and warmly bore testimony, “for nothing had,” he said, “tended more to his unhappiness than upon many occasions to have received compliments for the invention, or original idea, when he could assure the company he was totally innocent of it.”

The merit of another great suggestion which has also been acted upon in the construction of the Great Eastern is due to Mr. Brunel. This is the application of the tubular or cellular system of construction—before applied by Mr. Stephenson in railway bridges—to the hull of the ship. On this point, however, we must be very explicit. Mr. Brunel did not practically adapt this system to the new purpose; that is to say, the arrangement of the various parts of the ship's structure was not made by him. Nor does Mr. Russell fail to state as much. In the speech before referred to he says: “My responsibility was the construction, as a naval architect, of the lines of the ship. If the ship is slow, if she has bad qualities, the responsibility is mine alone; if in regard to her structure she is ill-made, ill-planned—if her materials are ill-disposed or ill put together—that is my fault; and if her engines do not, her paddle-wheel engine especially, work well—if her boilers are not equal to their work—then I am almost entirely the only man to blame. Messrs. Bolton and Watt are here to speak for themselves, and will take the responsibility of their own engines.”

Thus, with this wonderful ship in all its great features and complex details before us, we have to separate from her first the original conception of *such a ship*, and next the conception of a tubular or cellular mode of construction, and then all the rest is Mr. Russell's. That is to say, the ship itself, as a vast and novel mechanical structure, is his alone. The merit of the naval architect who designed her, the merit of the shipbuilder who built her, the merit of the engineer who placed her engines in her—all this merit is, strange to say, concentrated in one man. The abstract conception of her is Mr. Brunel's; the actual embodiment of that conception in the noble vessel which is so soon to see blue water is solely Mr. Scott Russell's. Surely no man could wish to have a prouder thing said of him!

Mr. Russell has frankly told us the secrets of his success in this unparalleled undertaking. With respect to the manner in which he had endeavoured to carry out his work, he had made, he said, a resolution which he was happy to say he had maintained—that he would not permit, so far as he was concerned, any new scheme, invention, or crotchet of his own to enter into the construction of the ship; and also, if possible, that no new, clever, or ingenious but untried invention of his friends should have anything whatever to do with it. He therefore confessed at once that there was no

novelty in the construction of the ship. In building her he had thought it the best and safest course to make the lines the exact shape of those of his previous vessels which had proved most successful—to make the mechanical structure an exact copy, so far as circumstances would allow, of those vessels which he had constructed, and which had been successful; and also to make the engines exact copies of those engines which he had built for similar purposes, but not upon the same scale. “There is not, therefore, so far as I am concerned, a single untried experiment in the whole of the structure which the company see before them.” There is sound wisdom displayed here. Mr. Russell is neither slow to invent himself, nor opposed to invention in others. But he has had the good sense to run no needless risks in carrying out the great work committed to him, and even to avoid the very appearance of what, though sure enough to his own judgment, might seem tentative or speculative to others.

Those who recollect what the condition of the Great Eastern was when launched, and who have this week seen her as she now is, will not fail to recognise in her rapid and efficient completion another ground for connecting the name of Mr. Scott Russell in the closest possible manner with the history of this great ship. It has been our good fortune to have opportunities of observing the progress of the works on board of her during the last nine weeks, and we hold it impossible to over-estimate the fertility of resource, the promptness of action, and the skilful disposition of men and material which have been displayed by the one directing and controlling mind. Knowing something of the manner in which our public departments are at present handled, and seeing what a single man has accomplished in this private enterprise, we do not wonder that men sometimes grow weary of the delays, the extravagancies, and the failures of the former, and sigh to see the swiftness, the economy, and the success of the latter imparted to it.

Now the Great Eastern is all but finished, it becomes our duty to fix our mind once more upon the true object with which she has been constructed. Trips to America and back can afford no kind of test whatever of the commercial success of this ship. Only continuous voyages of several weeks' duration—to India, China, or Australia, and back, for example—can give her a fair chance of proving her value. As she is to go down the river on the 21st or 23rd instant, and will make her trial trip early in September, it should be understood, as Mr. Russell said on Monday, that she never was intended for short voyages; and though she would be tested on a short voyage, she was not to be finally tried by such a trip. What the great ship must be tried by is that for which she was originally intended, viz., a voyage to Australia or India in thirty-three or thirty-six days. “It is most important,” said he, “to bear this in mind, because if our distant colonies can find themselves brought by the ship within thirty-three or thirty-six days of the mother country, they will not remain long satisfied without having a fleet of such ships, and without making such commercial arrangements as will admit of their being established to make regular voyages.”

There is another consideration connected with this unexampled vessel which must not be forgotten. Without in the least degree detracting from her commercial qualities, or increasing her cost, Mr. Scott Russell has so constructed her that no less than three hundred and sixty 10-ins. guns might be placed on board of her and fought, if the Government should at any time desire to convert her into a ship of war, either temporarily

or otherwise. This is no small matter. She is already, it should be understood, proof to ordinary round shells, and her speed will at least be fifteen knots an hour in all probability. Moreover, her bow is both fine and strong enough to secure her against material injury should she encounter a foe after the fashion of a "ram." She is likewise divided into numerous watertight compartments. We need take no pains to express what the value of such a ship, armed as we have said, would be to us, as a weapon of either offence or defence.

In many other ways this, the greatest of ships, is suggestive to us. She is, we believe, the beginning of a new era in ocean navigation, and this, if we mistake not, not as a mercantile agency only. But further consideration of this subject must be deferred. We must not, however, omit to notice the few sensible comments offered by Mr. Russell on the launching of the *Great Eastern*. There had been a great difficulty with respect to the launching of this vessel, he said. But the mode of launching had nothing whatever to do with the principles on which the ship was constructed. It was entirely an afterthought. The plan tried was one which, he considered, ought never to have been adopted. It would never, he hoped, be resorted to again for the launching of any ship. "The *Great Eastern* might have been launched with a great quantity of grease and oil upon smooth oak planking—a mode which succeeded every day in practice, and with respect to which there was no difficulty whatever. In future, therefore, whenever any large ship like this was to be constructed it would not be at all necessary to invent any new method of launching, but simply to adhere to the good old plan of the shipbuilders, of oak planking and plenty of oil and grease." This is precisely what we said at the time, and we only quote Mr. Russell's words for the sake of showing that the scheme adopted by Mr. Brunel was no shipbuilder's device, but purely his own.

THE DOCKYARD COMMITTEE OF ECONOMY.

ONE may write on great public topics for a year and never have his statements questioned, provided his facts be false and his inferences erroneous. But only let his information be sound and his conclusions certain, and he will inevitably be speedily and flatly contradicted to his face. Let no reader of ours suppose, therefore, that we expected our last week's article on the Dockyard Committee of Economy to pass unchallenged. Had we taken any other than a plain and simple course—had we turned our back upon facts and started into the region of fancy—had we shut our eyes and dreamed instead of keeping them steadily open and using them—then we might have written ourselves gray, and never elicited a sign, either of praise or dispraise. The great sin in all such cases is to know where the vulnerable point is to be found, and to aim at that. Strike there, and the wounded creature—even although it be an Admiralty Committee—must writhe and rage.

Now, had the Committee in question been properly constituted, it would have been invulnerable at all points. Had it been designed and framed for the honest purpose of ascertaining and correcting such defects as might have been found to exist in our dockyard establishments, and had that purpose been purely and faithfully carried out, any attempt to discredit its decisions—whether made by us or by others—must have brought only shame and confusion upon its authors. But it was not so. This Committee, as is well known, was not appointed in simple good faith. Mean aims and considera-

tions were mixed up with it from beginning to end. It was therefore both a bad and a vulnerable object, and it became our duty to assault it. This we did with earnestness, but at the same time with perfect fairness. We did not, of course, attempt to bludgeon the vitality out of it with mere angry speech. We intended that our blow should be fatal, if possible, and aimed it accordingly at a vital part. That vital part was, we admit, in a curious place. Like Paris, we had to drive our arrows at the heel rather than at the head or the breast of our Achilles. But, if our object was a just one, our means of attaining it cannot, we think, be questioned.

On another page we print a protest against our last week's article, from the pen of Mr. Murray. The only portion of this protest which greatly concerns the public is that in which he disclaims the "prominence" which he considers we have given to his "name." This is not exactly what Mr. Murray means, we presume, because his "name" had not, so far as we are aware, any considerable prominence given to it. What is doubtless meant is not the prominence given to his name, but the preponderance attributed to his influence. The context implies that this was intended, because we are told that we "have formed a very false estimate of the part taken by the other members of the Committee." In support of this view of the matter Mr. Murray does not give us the slightest assurance of the activity of these gentlemen in shaping the evidence received by the Committee, or in penning its Report. He contents himself with pointing out the antecedents of Admiral Smart and Mr. Laws, and referring vaguely to Mr. Bowman's experience. Admiral Smart, he reminds us, was Superintendent of Pembroke yard—a yard from which the great "repairing" branch of the shipbuilder's craft is almost wholly excluded, by the bye, and to which we believe the Committee never went—and Mr. Laws has been a clerk, a secretary, and a store-receiver. It may suit Mr. Murray's purpose to pretend that these circumstances are sufficient to fit the gentlemen in question to sit in judgment upon the whole art and mystery of the naval architect and shipbuilder, the engineer, the blacksmith, the joiner, &c. But we address a class of readers who know much better.

Let us consider, for example, the subject to which Mr. Murray himself alludes in his letter—that of the training of naval architects—and let us inquire what qualifications these gentlemen have for pronouncing, we will not say a decision, but an opinion even upon this question. By all who have the slightest claim to be consulted upon such a topic, it is held essential that the superior shipwright officers of a dockyard should be well skilled in the science as well as the art of ship-construction. But this science cannot be at all thoroughly studied without a preliminary mastery of many of the higher branches of mathematics. We have lately seen in our own columns that the rules by which the most elementary calculations of the naval architect are made cannot be conveniently investigated without recourse both to the differential and to the integral calculus. Every mathematician knows that many subjects must be gone through before even these are reached, and every educated naval architect is aware that these are by no means the limit of that which he has had to master. The difficulty is, then, to provide generation after generation of men trained in all the science of the naval architect, and fit also in other respects to become mechanical officers of the highest class, while, at the same time, they shall have had sufficient practical acquaintance with the work of the dockyard to enable them to conduct that

work efficiently. This was one of the most vital questions that called for the decision of the Admiralty, and this, we fearlessly assert, neither Admiral Smart, Mr. Laws, nor Mr. Bowman was in any sense competent to form a judgment upon.

Three methods of accomplishing the object have been proposed, and two of them tried. The first consisted in introducing a class of apprentices from a grade of society superior to that from which dockyard apprentices are ordinarily derived, and in affording them an exclusive training under masters and professors specially appointed for the purpose. The whole of the present master shipwrights of the dockyards (with a single exception) were trained in this manner. This first plan was incontinently put an end to by Sir James Graham many years since. The next method consisted in selecting by competitive examinations from the ordinary apprentices of the dockyard (all of whom, be it remembered, have been under the instruction of good schoolmasters for many years past) a very limited number of the most promising, and in sending these to Portsmouth to be trained by special masters and professors in all that pertains to the shipbuilder's profession. This plan was put in operation about eleven or twelve years since, and continued in existence only four or five years. The third plan is that which the Committee before us has proposed, and this consists in entering the sons of gentlemen in the dockyards, to be trained expressly for master shipwrights and assistant master shipwrights, all promotion to these offices being for the future almost exclusively reserved for these young gentlemen. Now, we have no space here to discuss the relative merits of these three systems with any minuteness; suffice it for us to state one great principle which we would lay down for our guidance in this matter. It is this: Seeing that no known or conceivable system of training youths can by possibility make all who are trained fit for responsible office, or can be expected to do more than turn out a small per centage of eminently able men, we ought to adopt a plan which will enable us to leave a majority of our trained men, if need be, in inferior positions without doing them injustice. In other words, we ought to adopt a system which, while it will furnish us with a goodly number of efficient officers in high positions, will saddle us with no bad ones. Any man of sense will see in a moment that the Committee's system will not bear this test. For every thoroughly good officer it would in all probability give us at least three bad ones, and thus largely help to ruin the service which it is vainly designed to aid. We may say much more on this important subject, but we cannot say it now.

We have thus far dealt with Mr. Murray's letter in its general aspect. There remain, however, a few words of another kind to be said. We have inserted that letter, not because the writer has any just claim upon us for the publication of a single line of it—for he in no way helps the public to form an altered judgment upon the merits of the Committee—we have given it a place simply because we see no reason whatever for refusing to comply with Mr. Murray's request that it might be inserted. What Mr. Murray's object is in the last half of it we cannot divine. One thing, however, we hasten to say respecting it, and that is, that he need not speak so bitterly as he does about our insinuations against his "character." Mr. Murray's character is not a legitimate object for our criticism, and we have not, we think, ventured to criticise it. If Mr. Murray will take the pains to calmly re-peruse what we said, he will find

that it amounts only to this, viz., that he appears to have, perhaps, a somewhat overweening consciousness of ability; that he was thought by some to have been too pliant to the desires of Mr. Corry; that he has no claim to be esteemed as a naval architect by the public; that as an engineer even he has not distinguished himself in any remarkable manner; and that he is guilty, perhaps, of a peccadillo or two in regard to the re-distribution of official responsibility in our dockyards. Now, to call statements like these a "personal attack," when they are simply directed against a member of a Committee, or to call them insinuations against a man's "character" when they are merely adduced as reasons for thinking lightly of an official report, is, we submit, to wrest language from its daily uses. Against Mr. Murray, as Chief Engineer of Portsmouth Dockyard, we have not a word here to say, much less have we a syllable to breathe against his character. All that we contend for, and all that we say is, that the Report in question is mainly Mr. Murray's, and that we have good reason for refusing to accept Mr. Murray's manifesto as a basis for great and sweeping changes in our dockyard establishments. We distinctly assert that we have made no attempt whatever to filch from Mr. Murray or from his colleagues "such good names as they have." All we ask is, that if he or they have any special claims to public esteem or homage, they will tell us so. We will gladly make them known.

There is one thing which, for Mr. Murray's own sake, we most sincerely hope: it is that his remarks about one of ourselves were not put forward with any paltry or vain desire to detract from the influence of our present labours by a reference to our mode of starting life. This part of Mr. Murray's letter is written in such peculiar English that we cannot discern exactly what he means. His statement amounts apparently to this—that he does not consider it necessary to reply to what we said last week, because we studied naval architecture under a system of which he disapproves! That appears to us a curious kind of announcement, and we doubt not it will appear so to others. On a question of this kind we shall, we trust, be pardoned for a remark that may appear somewhat egotistical; and we venture to say that the training which Mr. Murray seems disposed to put a slight upon, is precisely that which the *Times* lately put forward in repeated leading articles, as the ground upon which it based its confidence in our statements, and claimed for them the highest authority.

If Mr. Murray can really be so mistaken as to suppose that we are in the least degree sensitive as to our origin, we can only invite him to change his mind. We do not scorn his supposition; we merely smile at it. In this day, when nine out of ten of our eminent engineers and shipbuilders, to say nothing of other classes, began life in some form of apprenticeship, it is too late for any one to attempt to produce even a blush on such a subject, especially when intellectual competitions have, from the first, been the only steps by which a man has ascended. We do not ask where Mr. Murray sprang from, because we do not feel an atom of interest in the question, and because if we did we should have no right to make the inquiry. On the contrary, we would urge him to lose sight of such frivolous questions altogether. A man is now estimated, not by the station of his father, but by his own endowments; and Mr. Murray is perfectly welcome to the support of the few who think otherwise.

If Mr. Murray be fair and friendly he is free either to write to us in a suitable spirit or to remain silent. If he be hostile, and must fight, let him not babble of our boyhoods, but take

for his weapon what a Hyde-park orator lately called "the bright and cutting intellect." If he can then show us that his weapon is well-tempered, and wielded nervously, we will not ask him on whose milk he was suckled, or where his sword was forged.—E. J. R.

THE NEW MIXED METAL COINAGE.

It will have been observed by the public that the Chancellor of the Exchequer asked the House of Commons on the 4th instant for £10,000 only on account of the new coinage of bronze, instead of £50,000, which was the sum originally set down in the estimates. This wide departure from the original intention of the Government is puzzling, and we regret to say that the subsequent remarks of the right. hon. gentleman afford no satisfactory explanation of the change. Mr. Gladstone is reported—and no doubt accurately reported—to have said that, "when the operation of coining money of mixed metal was first contemplated, it was supposed that in order to carry it on with sufficient rapidity Government would have to purchase presses and supply them to the contractors; but on inquiry it was found unnecessary to do this." Hence, by inference, the reduction of the sum asked for. Now, there is something so completely contrary to the practice of the Government in the purchasing of machinery for Government contractors, and it must be added, contrary also to common sense, that we are quite at a loss to know who could have "supposed" such a course necessary in the first instance, or how a gentleman of Mr. Gladstone's sagacity could with gravity mention it in the House of Commons. Evidently there is another reason than this for the alteration, and in time possibly it may ooze out.

If the Government thought seriously about buying new coining presses, they would be most likely to erect them on their own premises, and not on those of other people; and certainly the cost of such machinery would soon be covered by the profits of the bronze coinage. Coining presses of the most modern and improved make cost about £200 each, and the Royal Mint itself contains only eight of these money makers. Forty thousand pounds—which is the extent of the reduction in the estimate—represents therefore the purchase-money of two hundred coining presses. Would Mr. Gladstone in seriousness invite us to believe that when the sum of £50,000 was jotted down in the Civil Service estimates, class 7, for the new coinage, he thought two hundred presses would have to be paid for out of it and supplied to the contractors? Surely not, unless he deems his audience much more credulous than it is. Why, two hundred coining presses, working at their minimum rate, would stamp into existence 12,000 coins of bronze, or any other mixed metal, per minute; 720,000 per hour; 7,200,000 per day; or between forty and fifty millions per week! But really, with all deference to the Chancellor of the Exchequer, we must say there is something preposterous in the whole story. Contractors would rather buy coining presses than receive them from the Government, and the Government would rest content with a fair price for the contractor's coinage rather than be "bothered" with finding machinery and complicating the bargain. There is a class of Her Majesty's servants whose duties lie partly afloat and partly on shore: to these the tale of the coining presses may be told.

The Minister's statement with regard to the deplorable condition of the existing copper coinage, however, was, as every person is aware, perfectly true; and the necessity for supplanting it was very forcibly demonstrated. It is not necessary to recapitulate Mr. Gladstone's

evidence on this point, for our columns have been the vehicle for conveying to the public a knowledge of all the disadvantages attending the present coinage, and earnest appeals to the Ministry for their correction. Reference, indeed, to a file of the *MECHANICS' MAGAZINE* for the past six or eight months might have saved the Chancellor of the Exchequer from some statistical errors into which he inadvertently and therefore pardonably fell. Instead, for example, of there being in circulation—as the daily press makes Mr. Gladstone assert—only £800,000 worth of the deteriorated and unsavoury coins of copper, weighing 3,500 tons, there is about £1,250,000 worth, weighing 6,000 tons. Again, the right hon. gentleman would certainly not have told the House of Commons, had he consulted our pages, that the 1 lb. of copper is coined at present into 26 pence, and proportionate numbers of halfpence and farthings, when, in fact, no copper monies coined in these realms have been so proportioned since 1823, when the Irish coinage of such pieces ceased. Twenty-four pence, forty-eight halfpence, and ninety-six farthings have been the rates of pieces to the lb. avoirdupois from that year to this day. Apart from these trifling errors, and the very grave one of reducing the vote to a point which makes it almost valueless in promoting the first movement towards a great reformation, there is not much to object to in the ministerial statement. The principles for which we have contended are agreed to by the Government; but about the means of reducing those principles to practice in a speedy and successful manner we as yet differ. We, for example, do not approve of putting any portion of the new coinage into the hands of contractors at all. At Calcutta, at Bombay, and at Madras, they are increasing the resources of the respective mints so as to render them equal to the demands likely to be made upon them. Why not do the same with the Royal Mint of London? Eight coining presses were erected therein in 1810, and eight are all that that establishment boasts in 1859, although the quantity of work required of them is fourfold greater now than then. At Calcutta they will presently possess twenty-four, at Bombay sixteen, and at Madras eight presses. Why not, with the new coinage before it, give the English Mint double its present number—sixteen? Ten thousand pounds' worth of mixed metal coins would, in such case, without the co-operation of Birmingham, soon pass into circulation, and the profits of the coinage would pay for the presses. With respect to the mixture of metal chosen for the new money, it may be said that in all respects it is a good selection. Copper, 95 parts; tin, 4; and zinc, 1, form together a hard, clean, agreeable-looking, and not bad smelling composition, and will show off the engraving and devices of the coins to great advantage. Of the sizes of the various denominations of coin something may be said, for it is a question of importance.

As we last week gave the exact and individual weight of the copper coins circulating throughout the British dominions, so it may be as well to give as a guide now their individual diameters. The British penny of the coinage of Victoria is decimally 1.335 inches in diameter; the halfpenny, 1.108; the farthing (identical in size with the sovereign), .863; the half-farthing, .688; the one-third farthing, .590; the quarter farthing, .515; and the oboli, .625. Now, in all probability the circulation of the colonial small coins will remain as heretofore; but since it is determined to lessen the weight of the three superior denominations, it would be right to reduce their diameters as well as their thickness, maintaining a proper proportion between

them. If the bronze penny was to be made of a diameter say 1·200 inches, the halfpenny 1·00, and the farthing ·800, there would be given, as we imagine, quite enough of superficies in each to afford ample room for the design of the engraver; and, supposing the 1 lb. weight of metal to be coined, as we think it will be, respectively into 48, 96, and 192 pence, halfpence, and farthings, there will be enough thickness to "get up" a bold impression upon them.

These pieces would be valuable, too, as measures, for 10 pence would, if placed flatly in line and in contact equal one foot; 12 halfpence would also equal one foot; and so would 14 farthings. This would be at once a simple and useful arrangement, and we offer the suggestion of it humbly to the Government. The profit of such a coinage as this would certainly be great, for whilst the market prices of the metals composing the bronze mixture would make it little more expensive than copper alone, it would be nominally of double the value of copper when coined. Thus, though a ton of the existing copper coin represents a value of £224, a ton of the new bronze coin would represent £448—a tolerably wide margin of gain for Her Majesty's minters.

THE MAIN DRAINAGE SCHEME.

Most of our readers will remember that, shortly after the "great bell" at St. Stephen's began first to vibrate through the heavy atmosphere of London, an honourable member considered that the proper time had arrived to make certain uncomplimentary remarks upon its lugubrious tones, and to propose that since it could not be made to sound more like an ordinary bell, it should be put a stop to altogether, and allowed to remain as a monument of mis-spent money, labour, and engineering skill. It is with some degree of apprehension that we look forward to a similar objection in the case of another great public undertaking, when it shall have been duly completed. Then, of course, we, in common with Members of Parliament and others, shall be better able to judge of its value and of the wisdom that prompted it; although, it is true, our judgment may be of little avail, and of that description which bears no relationship either to foresight or inductive observation.

A detailed account of the scheme of metropolitan main-drainage was lately given to the public in the columns of the *Builder*. It is not our intention at the present moment to enter into a résumé of the same; nor even to pay tribute to the vastness of the enterprise or the ingenuity of the elaborate contrivances at the pumping station, overflow chambers, storm outfalls and penstocks. Our admiration for each detail and for the magnitude of the general undertaking is lost in our bewilderment that such gigantic and perfect appliances should be employed to such an end as that proposed by the Main Drainage Committee and the Metropolitan Board, and tacitly sanctioned by the representatives of the nation at large, who delegated to these bodies their responsibility in the matter. With regard to this responsibility we are aware that Mr. Thwaites and his coadjutors are in the category of those great men who are answerable only to themselves and to posterity; and we accordingly look upon them with the same degree of awe and respect that would be inspired by any other impersonation of the power of good and of evil. Whether any incense save that arising from their own works will reward their herculean labours, they will at least possess the fame which men award equally to those who have done much for the advantage of their

species or for the contrary. If they fail, it will be in effecting great things. Their immortality will not be to live for ever in the vicinity of Greenwich, nor to feel the dearth which their splendid contempt of the speculations of theorists, respecting the annual loss of so many tons of phosphates, may produce throughout the land. Let civilization supply these phosphates from distant rocks, if they must exist wherever the waving wheat and barley is to spring from the soil; or let our cereals come from other lands—from France, for instance; their work is in the present, *après eux le déluge*!

In France they are managing these things better, certainly in regard to the future and its inevitable necessities—perhaps also with respect to the present; since no putrefying organic compound, no cholic acid from the human bile will now be allowed to evolve its sulphur in deadly miasma from the waters of the Seine. The intercepting sewers on either side of this river are already finished, and their contents, properly deodorised, and retaining all their valuable constituents for their due purposes in the economy of nature, are to contribute to the fertility of the surrounding land. Public opinion, when founded on the dictum of men of science—whose researches, based upon close investigation, accurate experiment, and exact deduction, have given to the world those facts upon which will depend the prosperity of nations—appears to be held in greater respect under the "enlightened despotism" of France than it is by the Boards and Commissions of our own free country. It is not from any want of general enlightenment that such plans as the Main Sewage Scheme are allowed to pass current in England. A Member of Parliament may inform us, in presence of the testimony to the contrary of Dr. Hoffman and Mr. Witt and of Dr. Letheby, that in his opinion the lime thrown into the Thames "has already been productive of a beneficial effect;" but apart from the evidence of one important organ of sense, everybody who has made any inquiry upon the subject knows that this is not the case, and that about 65 per cent. of organic matter is only removed by this means for a limited number of days or hours from its original sphere of decomposition. Our representatives, engrossed with many other important matters, may for an instant be arrested by the wonderful plan of a foreigner for concreting the bottom of the river; but the generality of the "intelligent classes" can better appreciate the difference, with respect to the practicability of this method, between the Thames and the lake in St. James's Park, and are more inclined to bestow their attention upon the more feasible arrangements proposed by Mr. F. O. Ward or Mr. George Coode.

Never yet, perhaps, was a public enterprise of a similar character begun and continued—we will not say ended—amid such universal reprobation as that which has attended the main drainage scheme. Every print within whose scope it falls has in turn raised its voice against the plan. Reprobation is far too mild a term to express the feeling with which men of science as well as the general public regard the gigantic blunder by which, at the enormous expenditure of money, and a sacrifice of time which in this instance is not money but life, the concentrated sewage of London is to be discharged at Barking Creek and Crossness Point. Execration would, perhaps, be a more appropriate word for that which met the birth and which follows the progress of this scheme in the minds of men who can realize the full enormity of the outrage against sanitary science, the well-understood laws of national agricultural economy, and common sense, which is comprehended in this measure.

THE REAPING MACHINE.

We have this season witnessed several successful operations with the reaping machine, and have to congratulate Messrs. Burgess and Key upon the important results thus obtained. We cannot, however, altogether acquit the farmers in some districts from a yet lurking shadow of prejudice against this mode of rapidly getting in their harvests. In many districts visited by us, the scarcity of labour was such that 25s. and even 30s. were being cheerfully paid for labour, and in others labour was not to be obtained at any price beyond that afforded by neighbours, the militia, and schools. Yet is this machine scarcely known in such parts; and where best known, we regret to add, fairplay is not altogether accorded to it. A field of wheat, of barley, or of oats, standing proudly before it, falls with a rapidity perfectly marvellous; and the bye-standers are not slow to testify their wonder and admiration. But let a portion of the crop be laid low by wind or storm, with the grain from the machine, and the machine must necessarily, from its very construction, pass over it. Here, then, is food for derision and prejudice. But is this justice? There is not a man amongst the spectators who, when on the beat of bone and blood, would put a horse to an impossible fence. Yet even this, which is apparently impossible with the machine, can be rendered facile if fairplay is accorded to it; for we have but to leave those portions of the crop thus circumstanced until the last, and then meet the difficulty in a rational way, and remove it. Indeed, there is not a portion of a crop that may not be cut if tact is exercised, and this tact will assuredly be accorded as the want of labour is more and more felt. The corn alone that has fallen out of ear this season, and which might have been saved had the machine been *in reach*, would have paid for its use in perpetuity upon many a farm.

We hear that the Royal Highland and Agricultural Society have awarded the first prize to Burgess and Key's machine. This is remarkable, inasmuch as no less than eleven Scotch, three English, and one American machine were opposed against it.

Amongst other extraordinary performances well accredited, is that effected upon a farm in Surrey, where 141 acres of wheat and twenty acres of oats were cut in eighty-eight hours by one machine at a cost of 4s. per acre. The small cost of the wear and tear of these machines is something equally worthy of notice. Alderman Mechi has used his reaping machine for eight years, and its annual cost has not exceeded an average of 2s. 6d. per year for repairs.

THE CASE OF HENRY CORT, AND HIS INVENTIONS IN THE MANUFACTURE OF BRITISH IRON.

BY
THOMAS WEBSTER, M.A., F.R.S., &c., Barrister-at-Law.
No. VIII.

To the "State of Facts" published in 1787, relative to the making of bar iron, by Henry Cort, is added, by way of Appendix, the following authentication of its contents:—

Extract from Lord Sheffield's "Observations on the commerce of the American States":—

"If Mr. Cort's very ingenious and meritorious improvements in the art of making and working iron, and his invention of making bar iron from pig iron, either red short or cold short, and the great improvements on the steam engines by Messrs. Watt and Bolton, of Birmingham, and Lord Dundonald's discovery of making coke for the furnace at half the present expense, should all succeed, as there is

reason to think they will, the expense may be reduced so greatly, that British iron may be afforded as cheap as foreign, even if the latter should be allowed to enter duty free, perhaps cheaper, and of as improved a quality, and in quantity equal to the demand. It is not asserting too much to say that event would be more advantageous to Britain than thirteen Colonies. It would give the complete command of the iron trade to this country, with its vast advantages to navigation; and our knowledge in the iron trade seems hitherto to have been in its infancy."

Extract of a letter from Doctor Joseph Black, Professor of Chemistry at Edinburgh, dated May 15, 1786:—

"I meant also to have explained to you my opinion of Mr. Cort's process of making iron; it is this: I have never analyzed the iron made by that process, as I always considered direct experiments to prove its toughness in its hot and cold state, as also its strength and other good qualities, as the most interesting and decisive trials, and I like the process, and the iron, for these reasons—

"First, it does not require the expense of charcoal, but is performed with raw pit-coal.

"Secondly, The iron is heated and wrought with flame only, instead of being mixed with the burning fuel and ashes, which is the case in the common process; and it is difficult to imagine how these extraneous matters can ever be completely disentangled from it again in the common process.

"Thirdly, Mr Cort's method of forming the bars by means of rollers is better fitted for squeezing and forcing out the melted slag from every pore of the iron, and, therefore, for giving such iron perfect solidity and close contact and cohesion of its parts more than the common method with the hammer.

"Fourthly, By the experiments made here, I saw that Mr. Cort's iron was exceedingly soft and malleable when hot, and very tough when cold; and I have heard of much more decisive experiments made in England, which prove it to be possessed of very good strength and toughness: for these I refer to Mr. Cort, who, I suppose, can give evidence of them. The only point which remains undecided with me is, whether Mr. Cort's iron can be afforded sufficiently cheap; and this point will be surely decided by any company who may establish works on his plan. I am informed that a great deal of bar iron is now made in England sufficiently cheap, by another process, in which also the expense of charcoal is avoided, but such iron is not of the best kind."

Extract of a letter from David Hartley, Esq., dated Golden Square, June 19, 1786:—

"Having heard that Mr. Cort had discovered a method of making the very best of iron out of common iron ballast, by a short and simple process, I went to his works, and, as far as I could judge, his invention appeared to me to be founded on simple principles, for reducing iron to its natural and heat state, by the expulsion of all heterogeneous and unmetallic particles; the fundamental principle being, that iron is in itself a simple homogeneous metal, and that all iron is equally good when purified from heterogeneous and unmetallic particles.

"The ordinary mode of converting cast iron into malleable iron is by the use of a very great quantity of charcoal, which contains what the chemists call *philogiston*, and which has the quality of remetalizing demetalized particles, which are mixed up with iron while in fusion. The method used by Mr. Cort is not by charcoal. He uses sea-coal entirely, because it is not his principle to remetalize any of the demetalized particles, but to expel them.

"The process, as I saw it three or four times over, is something to this effect: Between two and three cwt. of common iron ballast is melted in an air furnace with sea-coal. When melted, it spits out in blue sparks the sulphur which is mixed with it. The workman keeps constantly stirring it about, which helps to disengage the sulphureous particles, and, when thus disengaged, they burn away in blue sparks. In about an hour after melting the spitting of these blue sparks begins to abate (the workman stirring all the time), and the melted metal begins to curdle, and to lose its fusibility, just like solder when it begins to set; the cause of which I take to be this—the stirring not only disentangles the sulphur, but it gives opportunity for like to meet with like, by which means metallic particles meet and coalesce, never to separate again, and then they become unfusible. The unmetallic particles, which, being of a vitrifiable nature, contribute to flux the whole mass, are partly calcined and partly burnt away. The whole mass at the end of the first part of the process consists of metallic particles and dross sticking together, but not incorporated. The clotting of the metallic particles by the stirring about may be compared to churning. As the stirring of cream, instead of mixing and uniting the whole together, separates like particles to like, so it is with the iron; what was at first melted comes out of the furnace in clotted lumps, about as soft as welding heat, with metallic parts and dross mixed together, but not incorporated. These lumps when cold resemble great cinders of iron: they are called loops.

"The next part of the process is to heat these loops to the hottest welding heat in an air furnace, and to put them under a great forge hammer, which by a few strokes at the very highest point of the welding heat, consolidates the metallic parts into a slab of malleable iron, about three feet and a-half long and three inches square. The hammer at the same time expels and scatters the unmetallic dross. These slabs are brought to a wedge point at one end. They are malleable iron, but still with a considerable mixture of dross.

"The last part of the process is to heat these slabs to the hottest welding heat in an air furnace, and then to pass them through the rollers of a rolling mill; the slabs being extremely soft at the highest point of welding heat, the force of the rollers consolidates the metallic parts into bar iron, and the dross is squeezed out and falls under the rollers. This is the whole process; and thus in about six hours I have seen a piece of common iron ballast rolled into a ship's bolt; I have seen this bolt laid hollow across the eye of a large forge hammer and receive two hundred and fifty strokes of the heaviest sledge hammer, and thus bent double, but without breaking, or suffering the least apparent injury.

"I conceive the two principles of this invention to be, first, burning off and calcining the sulphur and the demetalized particles of ballast iron, instead of endeavouring to restore the demetalized parts with charcoal at a great expense, and still leaving the business undone; and, secondly, expelling the dross and consolidating the metal by squeezing it through the rollers, instead of the common mode of hammering, which requires a considerable length of time, during which time the metal loses the softness of a welding heat, and becomes too hard to suffer the expulsion of the unmetallic parts. The common mode, therefore, operates with much less effect than Mr. Cort's mode, because it operates upon a less degree of heat and softness. It consolidates heterogeneous particles into the body of the iron, instead of expelling them by the expeditious and forcible

impression of the rollers in the softest state of welding heat. It is to be observed, likewise, that the common blooms, as they are called, in ordinary forges of iron, are nearly three times as thick and solid as the slabs in Mr. Cort's process, and therefore much less affected by the blow of a hammer than his slabs are under the effect of the rollers. His slabs are small, soft, and ductile, and therefore easily suffer the expulsion of the dross by the squeezing of the rollers.

"These appear to me to be the principles of Mr. Cort's discovery. They appear to be conformable to chemical reasoning, and to the general principles of metallurgy. The demetalized particles of ballast iron, so demetalized by the sulphur in the ore, form the alloy of iron; when the sulphur is carried off by the fire, and by stirring the metal about while in fusion, and when the alloy of unmetallic particles is expelled by the application of the hammer and rollers in the softest state of welding heat, the metallic parts thus kneaded and consolidated together form the refined and homogeneous metal iron. Mr. Cort may therefore be said to have discovered for this country an immense iron mine above ground, as all pig iron and common ballast iron may by his process be purified into good metal. It is not improbable that this discovery may produce a great revolution in iron matters between imported and home-made iron.

"The proof of facts forms the basis of the case. The illustration which flows from the discussion of principles confirms the interpretation of the facts into proof of the merit of the invention; because those facts proceed through every stage of the process coherently with the principles which constitute the invention, and consistently with the general and acknowledged principles of metallurgy, and because the perfection of the metal results from the strict adherence in the operation to the principles of the process."

Extracts from Dr. Black's "Remarks on the Experiments made to Prove the Strength of Mr. Cort's Iron, dated Nov. 2nd, 1786":—

"The bar iron made by Mr. Cort was distributed to the different dockyards, and manufactured by the King's smiths into anchors, bolts, rings, hooks, and other articles belonging to shipping which occasionally resist very violent pulls, or support great weights; and similar articles were at the same time made of the best Swedish iron, as exactly alike to the former in weight, size, and form as possible. The experiments to compare the strength of the two kinds of iron were afterwards made by opposing an article made of the one to the similar article made of the other; and from the description of the experiments it is plain that they have been made in the most fair and decisive manner. The two kinds of iron were tried in each experiment with the same force or strain gradually increased until one of them gave way, which, however, did not happen in general until after the strain was increased to a far greater degree than any to which the same articles are exposed in actual service.

"When we sum up the results of these experiments, it is evident that Mr. Cort's iron is superior in strength to the very best Swedish iron; for such alone was employed on this occasion.

"There were six comparative trials of anchors; Mr. Cort's iron was found stronger than the Swedish in five of these trials.

"The comparative trials of hooks and iron-bound blocks were twenty-eight in number. Mr. Cort's iron proved stronger than the Swedish in ten of these trials; equal in fifteen; weaker in three only.

"And even of these three two were not quite equal, viz., the trial at Woolwich of second-sized hooks, and second trial of top-tackle iron-strapped blocks at Chatham.

"The comparative trials of bolts in driving and in holding fast were fourteen. Mr. Cort's iron proved the stronger in three; equal in seven; weaker in four.

"But in one of these four experiments, viz., that with the P bolt at Plymouth, 5th of August, there was a defect in the workmanship of the bolt made with Mr. Cort's iron. And it must be remembered, that in all these trials the strain applied to the different articles was far more violent than any to which they are exposed in actual service except the driving of bolts; and in this operation Mr. Cort's iron had the superiority. The general result of these trials, therefore, gives full conviction of the excellence of Mr. Cort's iron."

Another important class of testimony to the success of the invention is afforded by the agreements entered into with, and the conduct of those engaged in the same manufacture, who must be presumed to have been alive to the importance of the subject, and be competent to form a judgment thereon.

Among the persons competent to form such an opinion, William Hawks, of Gateshead, would be prominent. By agreement, dated the 29th of May, 1784, between Cort and Hawks, after reciting the grant of a patent 13th of February, 1784, the second patent, and that Cort had informed Hawks that part of his invention consists in the making of pig or other cast metal whether of a cold, short, or other quality into tough merchant iron without either coke, coal, or charcoal, and without blast of bellows or cylinders, which was never before known or practised in Great Britain; and that the said Hawks was desirous that the said Cort should make known to him the said invention;—it was agreed, for the consideration stated, that Hawks should have the privilege of making pig or other cast metal, whether of cold, short, or other quality, into tough merchant iron, without either coke, coal, or charcoal, and without blast of bellows or cylinders, paying 20s. for every ton of malleable iron shingled into half-blooms, slabs, or other forms proper for making into tough or merchant iron, each ton to be accounted to weigh 2240 lbs. weight. The agreement contains clauses for accounts, &c., and against his making known to any person the manner of practising the invention, for determining the agreement, and for a penalty; and a memorandum annexed, that instead of the 20s. per ton specified therein, one-third of the sum saved should be paid by Hawks to Cort for every ton of iron manufactured into bars or uses of merchant iron. Other similar agreements, reserving royalties of variable amount, and conditions under special circumstances, were entered into with Messrs. Brodie, Crawshaw, Cooke, and most of the principal iron masters, which, but for the unfortunate sequel, would have yielded a princely return to the meritorious inventor and those associated with him in introducing the invention.

It may be presumed that Cort shared the fate of most, if not all other inventors in having the validity of his patent questioned so soon as the success of the invention was established; and the following opinion of Mr. Justice Chambre, when at the bar, will be perused with interest.

"To establish a right to the monopoly of an invention under letters patent two things are necessary. 1st. That the invention is new, and not laid open to the public at the time of obtaining the patent. 2ndly. That the invention be sufficiently explained in the specification so as that persons of competent skill in the arts,

as practised before the improvement, may be thereby sufficiently instructed in the principles of the new invention, and enabled to put it in practice.

"The application of these rules of law would be better made by an artist than a lawyer, as his knowledge of the art would better inform him how the matter of fact is established by evidence; and the questions will be merely matters of fact, for the law is clear. As far as I can judge, the specification is unexceptionable. I think, too, under all the circumstances, that Mr. Cort appears to be the first person who perfected the discovery, and consequently that his patent is valid. However, this is a point upon which no very decisive opinion can be formed without knowing what can be offered in proof of the discovery being of older date. The idea of applying an air furnace certainly is not new, and the principal parts of the process appear to have been practised before, and perhaps the very mode may have been hit upon; but it does not signify how near the discovery former experiments have arrived, or even that they have produced the effect, if the persons practising these experiments have not known to what their success in a particular instance has been owing, and have been unable to practise or communicate any certain method of attaining the object. I take for granted that workmen will be produced to prove that the invention is not new, but it is so improbable that opulent companies engaged in the business of manufacturing of iron should neglect such a source of profit if they knew of it, and that it should be considered by scientific men of the first eminence down to the time of Mr. Cort's patent as a great desideratum in the art yet unattained, that I should suppose that sort of evidence would either be weak in itself, or would not receive much credit. If Mr. Cort's patent has any validity I think it will exclude the Coalbrook Dale Company as much as any others, for their patent is of no importance unless they had discovered the process, and if they had, then, whether it was described in their specification or not, Mr. Cort's patent would be of no validity. It seems to me that if Mr. Cort determines to enforce his patent, and to bring actions for infringements upon it, he had better contend with that company than with any others; for their conduct affords many circumstances which could not so well be given in evidence in a contest with others, and which may be very material; and besides, if Mr. Cort proceeds against persons setting up a rival patent, and pretending the merit of first discoverers, it is not very likely that others will hereafter contest the point with him.

(Signed) "A. CHAMBRE, Gray's-inn.

"4th March, 1785."

The Carron Company, by letter dated the 18th of February, 1786, invite Cort to their works:—

"Carron, Feb. 18th. 1786.

"John Wauchope, Esq.

"SIR,—We have taken into consideration your letter of the 9th, respecting our engaging to manufacture bar iron under Mr. Cort's patent. Should he enter into contract with Government for the furnishing of that article, we now beg leave to acquaint you that we should be very ready to accommodate Mr. Cort with our works in the following manner:—

"We would, in the first place, sell Mr. Cort our pig iron to any extent he may have occasion for at a stated price, and deliver it at the forge.

"In the next place, we would either rent him out the forge for a certain sum of money annually, or if it were thought more eligible at a fixed rate per ton on the quantity of iron

manufactured. In either case we would uphold the forge and make good the wear and tear.

"Mr. Cort should then have the entire direction of the forge, both as to the mode of his operations and as to the workmen that should perform them. He might either bring down his own people or take such of ours as would answer his purpose. In this situation Mr. Cort would be perfectly at ease and undisturbed as to his pursuits; and he alone would be answerable for their success.

"Under such circumstances Mr. Cort might make use of our name to the Public Boards in order to convince them of his abilities; to deliver the quantity he contracts for; and no doubt it must be from a connection with such extensive works as ours that he can prevail upon the Board to entrust the supply of their yards to a British manufacturer of bar-iron.

(Signed) "C. GASCOIGNE"

The following letter from James Black, the brother of Dr. Black, to Lord Stanhope, affords independent testimony as to what was going on:—

"23 Mincing Lane, May 24th, 1786.

"MY LORD,—By your permission, I have the honour of waiting on your lordship with the enclosed letter from my brother, containing his reasons for approving Mr. Cort's process to make bar iron.

"I was with Mr. Cort yesterday two hours, who related to me that a quantity of ballast iron had been delivered to him by order of Government, which he had converted into bar iron under three of their inspectors. That several anchors had been made at and in the principal dockyards; and other chain-bolts, &c., &c., of the said iron. That similar anchors, &c., had likewise been made of the best Swedish iron called Orgrounds. That comparative trials have been made at several of the dockyards. Mr. Cort, from the minutes he has taken, and which he showed me, has the fullest proof by experiment of his iron possessing every quality of the above-mentioned Orground Swedish iron, and of its surpassing the quality of that iron in toughness and strength. Mr. Cort proceeds to Portsmouth and thence to Plymouth, where he has reason to expect the same result in his favour, as the iron is the same. I took the liberty of mentioning to Mr. Cort that I had no doubt of his having established by the fullest experimental proof the quality of his iron; but that it now remained with him to establish the cheapness of his process by comparative experiments equally well ascertained. He said that so soon as he had finished what he was about he would immediately set himself to prove the cheapness of his process; in which he said he had no doubt of his success, upon grounds as incontestable as those on which he has established the good quality of the bar iron manufactured by his process.

"I hope this communication may be agreeable to your lordship, and I have the honour to be very respectfully,

(Signed) "JAMES BLACK.

"P.S.—Your lordship will be pleased to return me my brother's letter."

The *Scientific American* states that one of the newly-constructed locomotive steam fire-engines lately ran twenty miles on a common road. The whole weight of the engine, water, and nine passengers, was 12,000 lbs., 9,000 lbs. being the weight of the engine alone. The first three miles were made in sixteen minutes running time, and it went over a bridge 350 feet long, with a draw of forty feet in the centre, and up a very heavy grade, making 1,000 feet in exactly one minute. The time occupied in travelling the twenty miles was two hours, grades and all included.

THE WESTMINSTER CLOCK.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—It is now more than two years since the controversy between Mr. Denison and myself concerning the Westminster clock and bell appeared in the *Journal of the Society of Arts*, the *MECHANICS' MAGAZINE*, *Builder*, and some of the daily newspapers. That controversy, which was commenced in November, 1856, in the magazines, contained suggestions which would have prevented the principal failures that have since occurred if the Government had acted upon them. Some of the subsequent failures have become public; but the persons responsible for them have ungenerously shifted the blame from their own shoulders on to others. The question of who is responsible for the failures was mooted in the House of Commons on Friday, 15th July, and as no satisfactory answer was elicited, I purpose supplying the deficiency to some extent in this and a subsequent letter. And in doing so, perhaps I should claim some credit for forbearance when the first bell was broken, in not then calling attention to the fact of the bell having been destroyed by the clapper, which, throughout the last controversy, I had pointed out as being so enormously heavy compared with the weight of the bell and the size of the clock that was to work the equally disproportionate hammer. A reference to the publications already mentioned will show that the *tone* in which my statements were contradicted was sufficient to have justified the earliest opportunity being taken of recurring to the subject after events had confirmed my opinions.

The easiest way of arriving at the difference between what the clock was to have been and what it really is, will perhaps be to go through the excellent conditions originally laid down by the Astronomer Royal for the construction of the clock, and select the chief of those which have not been fulfilled. The first condition not fulfilled is the one which required the wheels to be made of hard gun-metal, with the teeth cut to the epicycloidal form. Instead of this the wheels have been made of cast-iron, which is the cheapest material that could be used, and the teeth have been cast in, instead of being cut, whilst a large sum has been added in the contract for the change, under the plea of the extra labour required in cutting and working cast-iron: whereas it now appears that the wheels are destitute of the promised workmanship, and that they are merely left from the casting. These deviations have been effected at Mr. Denison's instigation, and he is the person responsible for them. A second condition required the escapement to be the dead beat or something equally accurate. Instead of this the escapement employed is a modification of the gravity escapement, which in its most perfect form has occasionally been proved to fail even for small astronomical clocks; and as the power in the Westminster clock must of necessity be some hundreds of times greater, its employment there is certain to result in failure. For this deviation Mr. Denison is responsible. A third condition required that the minute hands should move over the half minute or minute space at once, so as to enable the time to be observed outside within a second. The plan for carrying out this condition has so completely failed that the condition itself has been abandoned. Mr. Denison designed the plan and is responsible for its failure. The forfeiture of this condition is remarkable, for it is the one concerning which Mr. Denison ridiculed Mr. Vulliamy for hesitating to carry it out. A fourth condition required that the first blow of each hour should be accurate to a second of time. To fulfil this condition the going part should be capable of keeping time within a second for 24 hours at least; but the pendulum is only compensated with zinc; and the enormous surplus force required to drive the hands in all weathers will occasionally reach the escapement and cause it to trip or run forward, and the hands to be in error, to the extent of either seconds, minutes, or hours, as the case may be; thus introducing a source of inaccuracy to which gravity escapements are especially liable, and one from which the dead escapement is entirely free. Mr. Denison is responsible for the plan adopted. A fifth condition required the clock to go and strike eight days with once winding up. Instead of this the arrangement had failed to the extent of reducing it to a four day clock some time since, with the probability of its requiring to be wound up still oftener. For this failure Mr. Denison is responsible.

Another condition appeared in the agreement with Mr. Dent which required that the clock should be completed and going 19 months in its place to the satisfaction of the Astronomer Royal and Mr. Denison before being paid for; and by finished and going it was of course understood that all the parts of the

clock were included, namely, quarter part, hour part, and going part. Yet, notwithstanding this, Mr. Denison gave his certificate, and caused nearly the whole of the contract money to be paid to Mr. Dent's successor more than two years before the clock had been fixed in the building at all, under the plea that the going part alone had been acting satisfactorily in Mr. Dent's shop waiting for the bells; but this was without either the hands and *motion work* or the hour and quarter parts being attached, and under none of the disadvantages of strong winds, snow, and frost, which will exert considerable influence upon them when at their great elevation. In fact, to have taken the trial in Mr. Dent's shop as the test of what the clock was capable of doing, was like trying a locomotive for its power without attaching any train to it, and taking the speed it was able to attain as the result which might be expected when encumbered with its complement of carriages.

The last failure publicly announced is the extreme weight of the minute hands, which the first commissioners of works has stated in the House of Commons to weigh more than 3 cwt. each. This weight for a minute-hand of only 11 feet radius is incomprehensible, even when allowance is made for the fatality which seems inseparable from the Westminster clock. Instead of 3 cwt. the hands should not have weighed 1 cwt. each; and if the metal had been disposed in the best form for giving the greatest strength with the least weight, they would have been amply strong enough with considerably less than 1 cwt. of metal in each. The First Commissioner of Works added that lighter hands were about to be made, and that it was probable the clock would then work all the four dials in a satisfactory manner. But this anticipation, like others of the past, will certainly be disappointed, for, after computing the weight which suitable hands, counterpoises, motion work, &c., must necessarily amount to for four dials of this size, and allowing for the additional influence of high wind, frost, and snow, the force required to overcome the whole will be so great compared with the weight of the pendulum, and the small force which will be capable of disturbing its time, that there does not appear to me any possibility of the clock maintaining a constant rate within several seconds a day, even though a dead escapement should be substituted for the gravity escapement to prevent tripping, and supposing the clock can be made to go continually thereby. And considering further that other sources of error will prevent the pendulum being increased so as to meet the difficulty, I am quite convinced that a clock with four dials this size can only be made to keep a rate within a second a day, by a similar plan to the one patented by myself, which I submitted to the Astronomer Royal for adoption in the Westminster clock several years ago; but Mr. Denison had then so far usurped the control over the clock as to prevent any plans being adopted besides his own. In this plan the power employed to drive the hands is completely cut off from the escapement and pendulum which regulate the time, and a small astronomical clock, with all its accuracy and durability, is employed for the time-keeping part, whilst the power available in the large clock for driving the hands may fluctuate even to the extent of 100 lbs. at the diameter of the centre wheel without affecting the time half a second a day. The plan, moreover, allows the Astronomer Royal's condition to be easily fulfilled for enabling the time to be observed to a second by the exterior minute hands moving quickly over the space of 1½ inches once a minute.

The difficulty that was likely to occur from Mr. Denison's plan of regulating the going part by a gravity escapement in direct communication with the hand *trains*, was pointed out to the late Commissioner of Works last February, and in the same letter I offered to undertake the superintendence of the clock, in order to introduce the improvement just mentioned and carry it to successful completion, but the reply seemed to indicate that the Board had not then power to change the superintendence. In fact, Mr. Denison boasted in his book, nearly two years ago, that the Board had taken no less than five opinions from the Attorney General, the Solicitor-General, and the other law officers of the Crown, to try and "get rid" of his superintendence without being able to do so, and the parliamentary papers show that the law officers were consulted with that object in view.

Concerning the cost of the clock, a great deal of credit has been claimed for the lowness of Mr. Dent's tender as compared with those of Vulliamy and Whitehurst, and the difference between them has formed one of the principal reasons for giving the contract to Mr. Dent; but we now see that the clock once secured, with Mr. Denison as referee, all idea appears to have ceased of its being carried out according to its original conditions, upon which the others

tendered, and a much easier way is adopted of making up for the low tender. Mr. Denison, having fairly established himself in the double position of designer and referee, acting professedly for the Government, begins the process by causing the material to be altered from expensive gun-metal to cast-iron, and the contract price instead of being lowered, to be raised from £1,000 to £1,900, partly under the plea of iron being more expensive to work, and then the next step is to dispense with the said workmanship altogether, but retain the full price in the contract, thus evading not only the original workmanship which gun-metal wheels would have necessitated, but the additional labour of cast-iron, for which the extra sum was added. And then, as each failure occurs in the plans of Mr. Denison, the *designer* and the Astronomer Royal's conditions of construction are sacrificed after each other; Mr. Denison the *referee* is ever ready to put a bold face on the matter and pronounce the sacrifice of the conditions as really the best thing that could have happened, and modestly intimates that the Government is fortunate in having the man "who understands the subject better than any one else in England." Mr. Dent's original estimate for the entire clock was, as we have seen, £1,600, but what the sum may have reached under Mr. Denison's management, now that the principal advantages of the clock have been sacrificed, there is no available evidence at present to show.

Having briefly sketched the failures that have occurred and those which are likely to follow, with regard to the clock, and shown who is responsible for them, I purpose giving a similar sketch concerning the bells in my second letter.

Yours, &c.,
30th July, 1858.

E. T. LOSEBY.

THE NEWCASTLE PUMPING ENGINE.

GENTLEMEN,—It is impossible to help admiring the beautiful simplicity of this engine, as described in your last Number, but I cannot imagine why the double-acting pump was not placed behind the steam cylinder, instead of in front of it. An ordinary horizontal high pressure expansive and non-condensing engine might have been used with some advantage, the piston rod being carried through both ends of the cylinder, and connected by some tolerably good non-conductor of heat to the end of the pump rod of the double-acting pump placed behind the cylinder. By this means the present difficulty of the connecting would be obviated, and the usual tendency of an horizontal cylinder to wear oval would be greatly diminished by the stuffing-box at each end of the cylinder being bushed with brass, and receiving a good part of the weight of the piston. W. H. C.

London, August 10th, 1859.

ASSOCIATION OF FOREMEN ENGINEERS.

On Saturday night last this Association met at their rooms in St. Swithin's-lane, City, Mr. Joseph Newton filling the chair. It had been announced that a member would read a paper on "Superheated Steam," and as this happens to be a subject of peculiar interest to the gentlemen who comprise the Association, a very numerous body assembled on the occasion. A disappointment, however, was in store for them, for after the ordinary business had been gone through, the Chairman announced that a letter had been received a day or two previously from the promiser of the paper, stating his inability—from illness—to redeem his promise. Mr. Newton, however, further announced, much to the satisfaction of his auditors, that under pressure of the emergency he had summoned to his aid the services of a friend, a fellow-member, who at the eleventh hour had nobly come forward and written a paper on a totally different matter, the "Manufacture of Rifles, with a description of those death-dealing weapons," which he was prepared, if acceptable, to read. Consent was readily given, and the gentleman, whose maiden attempt it was, and whose modestly declined to have his name published, read his very elaborate paper on this subject. It was at once a clear, practical, and tersely written essay, and conveyed much information of a novel character to the bulk of the members. At its conclusion the applause was general, and after a very enlivening discussion, in which Messrs. Keyte, Ives, Stabler, M. Jones, the Chairman, and others joined, a vote of thanks was given by acclamation to the expounder of the rifle. Mr. Newton, in proposing this vote, took occasion to eulogise the writer of the paper, and to incite other members to emulate his zeal. An adjournment to the first Saturday in September followed, and the meeting was at an end.

JENSEN'S MARINE ENGINE GOVERNOR.

FIG. 1.

FIG. 2.

FIG. 3.

JENSEN'S MARINE ENGINE GOVERNOR.

By Mr. PETER JENSEN, of Copenhagen.*

THE engines in very large screw steamers with deep draught are considered to work with sufficient regularity even in a gale, as the size and weight of the ship to a great extent prevent it from pitching; and for this reason no great difference in the depth of immersion of the screw takes place: but, except in the above case, serious irregularity is experienced in the working of marine engines in a heavy sea, when the screw or the paddle wheels are one moment deeply immersed and the next moment revolving half or more in the air. A waste of power then occurs; for although in a given time the same amount of power is supplied from the boiler, whatever the speed of the engines may be at any moment, still the power is not exerted in an advantageous manner whenever the propeller is only partially immersed, as it then presents too little surface of resistance to the water, and is consequently not able to propel the vessel so efficiently as when immersed to the proper depth. In most marine engines, therefore, instead of the consumption of steam being reduced by saving the steam when it cannot be used to advantage in consequence of the propeller being only partially immersed, it is at that time wasted in driving the screw or the paddle wheels with great speed in a light draught of water, and a great amount of slip or loss in effective speed of the vessel consequently ensues. In applying a governor to marine engines economy of power must result, as in the case of stationary engines. Moreover, most of the accidents occurring to marine engines are due to the sudden shocks that will happen during a gale even in well-balanced engines. The lubrication is also often rendered difficult, because the oil is thrown out of the cups; and the great amount of wear and tear in marine engines may be attributed partly to the shocks and the irregular motion, and partly to the more imperfect lubrication.

Marine engine governors have been attempted on several occasions, but only very few are yet applied. An ingenious modification of the ordinary Watt's centrifugal governor has been employed for this purpose, Silver's four-ball governor, in which the action of a spiral spring is substituted for that of gravity, and the whole apparatus is balanced so as to remain undisturbed in action during the pitching of the vessel. But the mode of action of all such governors is by checking the supply of steam to control the speed of the engine after it has begun to change either to quicker or slower: and it has appeared to the inventor of the governor forming the subject of the present paper,

that the principal desideratum in a good marine engine governor is an instantaneous action, so that whenever the screw or the paddle wheels are going down in the water more steam may be admitted to the engines as quickly as possible, and in the opposite case the admission of steam may be as quickly as possible checked, before the speed of the engines has been sensibly affected. For attaining this object it seems more natural to make use of the cause of the evil as a remedy against it, or to employ the irregular motion of the vessel as a means of regulating the engines, than to let the engines regulate themselves. By this means an intermediate step is dispensed with: and by making use of the non-elastic water as the motive power of the governor, the action will be exerted quickly enough upon the engines to regulate the supply of steam before the depth of immersion of the propeller has been materially altered by the pitching of the vessel.

The construction of the new Marine Engine Governor is shown in the engravings. Fig. 1 is a transverse section of the vessel showing the governor in position; and Figs. 2 and 3 are a longitudinal section and elevation of the governor enlarged. A cylinder *A* is placed at each inner side of the vessel below the water line, the bottom of the cylinders communicating with the water outside by means of the Kingston valves *B*. Each cylinder is fitted with a piston *C*, which is loaded with a spring *D* either of steel, compressed air, or india-rubber. The piston rods *E* act upon bell crank levers *FF*, and by means of connecting rods *G* motion is given to a common spindle *H*, from which the throttle valves of the engines are worked in such a manner that when the pistons *C* go down the throttle valves are closing, and when the pistons go up the valves are opening. Now as the pressure of the external water increases in proportion to the depth when the openings of the valves *B* come into different depths in consequence of the pitching or rolling of the vessel, the pressure on the pistons *C* will be changed proportionately; and to each pressure will correspond a certain position of the pistons and of the throttle valves connected with them. Omitting the pitching of the vessel in a paddle-wheel steamer, and considering only the rolling motion, it is obvious that when one paddle wheel is deeply immersed and the other nearly or entirely out of the water, the pressure on the two pistons will be different; but supposing them connected together, the position of both and of the throttle valves will be then corresponding to the difference of resistance on the two paddle wheels.

If these cylinders are placed as near to the propeller as convenient, so as to ensure pretty nearly the same depth of immersion, it will be seen that

this apparatus will then act as a governor for the engines: for when the propeller is revolving in a light draught of water, the supply of steam to the engines is proportionately diminished; and when revolving in deep water, the supply of steam is proportionately increased. The whole arrangement is simple, as shown by the drawing, and the cost small, probably not exceeding four or five shilling per horse power.

THE SCIENCE AND ART DEPARTMENT.

THE sixth Report of the Science and Art Department of the Committee of Council of Education was printed on Friday in the form of a blue book of some 150 pages, compact and portable. The geological survey of the kingdom is first noticed. The number of square miles surveyed in the past year, in Great Britain, has been 2,326, while in 1857 the area was 2,605. In Ireland the work of survey has been chiefly directed to preparing for publication the 1-inch maps of that country. Professor Huxley and Mr. Salter have worked diligently in the "Natural History" and "Palaeontological" departments of the survey. The Museum of Geology was visited by 24,877 persons last year. The Mining Record-office continues to increase in importance and usefulness. The Government School of Mines is prospering, and several kinds of assistance have been afforded to other departments of Government by Dr. Hofman (the lecturer on chemistry) and Dr. Percy (the metallurgical professor). One of the pupils of the school, a Mr. Charles Gould, has been appointed to the office of Geological Surveyor of Tasmania. The Museum of Irish Industry was visited by 23,638 persons. The number of visitors at the gardens of the Royal Zoological Society exhibits a large increase, a result attributed by the hon. council to "the increased attraction which a large addition to their stock of animals has enabled them to bring before the public." The various local schools of art, drawing, &c., appear to be flourishing, and the Metropolitan Public Schools for the Poor are growing rapidly. The Circulating Art Library of the South Kensington Museum was open for 289 days last year, and is very extensively used; 500 volumes have been added to the collection, and upwards of 1,300 prints and 600 photographs acquired. The Circulating Museum Collection visited six towns last year, and proved very attractive. The Museum at Kensington is replete with objects of interest, almost too numerous even to be glanced at in passing. The high rate of attendance at this Museum was fully maintained in 1858. A monthly average of 38,000 was maintained, and the total number for the year are upwards of 456,288, of whom

* Read at a late meeting of the Institution of Mechanical Engineers.

WOOD AND ROGERS' BOAT-RELEASING APPARATUS.

47,082 attended on what was called "students'" (not free) days; 237,272 attended in the day, and 219,016 in the evening. The public lectures appear to be useful and instructive. The results of the working of the Department of Science and Art in all its divisions, for 1858, exhibit a great increase on the previous year in the attendance of the public at the museums, schools, and lectures. The visitors to the various museums, &c., in the three capitals of the United Kingdom, under the superintendence of the Department, amounted to 875,898, equivalent to an increase of 117,923 on the previous year. The committee can state with confidence that at no period since the Department has been founded have its condition and working been so sound, or the public appreciation of the advantages which it offers in aid of private efforts to promote science and art among all classes so marked as in 1858.

WOOD AND ROGERS' BOAT-RELEASING APPARATUS.

THE accompanying engravings illustrate a new arrangement of apparatus for disconnecting both ends of a ship's boat simultaneously from the lowering tackle, invented by Mr. Wood, an officer of the Peninsular and Oriental Company's ship *China*, and Mr. Rogers, of Green's Dockyard, Blackwall. In the opinion of Mr. Wood, as he informs us by letter, the manœuvre of disconnecting the boats when lowered by the tackles within a safe distance from the water should be left to the judgment of the boat's crew, according to the rolling of the ship and the prevailing state of the weather. "My method," he says, "does not embrace the lowering of the boat, presuming that to be under control of careful hands on the ship's deck. I will, if required by any patrons of this method, so arrange the boat-tackle falls inboard the ship, by connecting them on one roller or leading through a block, as to insure the falls easing off equally and together, thereby compelling the boat to lower on an even keel; and, by shortening the stern rods of the after end of the boat, cause the after slings to be thrown off slightly in advance of the bow slings, and allow the boat to enter the water a little by the stern." "I have brought this out," he adds, "as a practical nautical man, and from experience of other methods in use have adopted this for security and

less risk of losing boats from the davit-head suddenly altogether."

It can hardly be necessary for us here to discuss the relative merits of the two methods of releasing—by the lowering fall, as in Mr. Clifford's plan, or by an independent apparatus as in Captain Kynaston's, and the new plan now before us. For some time to come, officers will doubtless be found to prefer each of them.

The engravings show the new plan very completely.

A is the norman or lock bolt to be withdrawn whilst lowering from the davits. *B* is the lever handle for heaving round the barrel, by which action simultaneously four rods or bolts are withdrawn from either end, setting free the slings by which the boat is suspended. *CC* are the long rods or bolts that are worked by the barrel, secured to the sides by staples or cleets as required. *DD* are the slings; they can be made of rope-wire, rope, or bar-iron, with eyes in each end to receive the bolts. In lowering the boat, if the ship is under way, the after-tackle should be lowered slightly more than the bow-tackle, so that the rudder may have all power over the boat to sheer her off immediately from the ship's side, and clear her if the ship is propelled by a screw; if the screw enters the water on the side the boat is hung, it is more liable to suck the boat towards the propeller, and *vice versa* if the ship is going astern or reversing with the engines. The boat should be let free from the tackles when about one foot or nine inches clear of the water.

BOAT-LOWERING APPARATUS.*

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—Having candidly admitted the unfairness of continuing to publish correspondence attacking me when unauthenticated by the name of the writer, and having stated your intention to decline doing so again, I shall of course confine myself, as far as this subject is concerned, to answering once more, and for the last time, what "Nauticus" advanced in his last letter to you.

When he first alleged the loss of a boat's crew through the use of my lowering gear, I challenged him to name the instance to which he referred. He replied by stating that it occurred to Messrs.

* Space could not be found for this letter in our last Number, or it would have appeared there.—Eds. *M. M.*

Green's ship, the *Orwell*, that "the fore pendant hung when the boat was at the water's edge, and the whole of the crew were drowned in consequence." On the authority of Messrs. Green (after they had themselves instituted inquiry into the circumstances), and also on the captain's, I showed that this statement was not true, and that the accident to the boat's crew was "*not in any way attributable to my lowering gear*." Any further particulars would have been merely superfluous, but it appears to have answered the purpose of "Nauticus" to relate the details of the catastrophe over again, and still to labour to attribute the cause to my lowering gear.

It certainly is a fact that ought not to be lost sight of, that the entire exculpation of my plan on the occasion in question proceeds from a firm that never used it through any feelings of friendship to me, or interest in the invention itself, but under the compulsion of Government. I may therefore justly claim the full value of all they state in my behalf. Evidence from such a source cannot be summarily set aside by mere assertions, even if advanced by "an original informant of rank and position" (but whose name, like that of "Nauticus," is withheld), and who, by the showing of the latter, stated one untruth at least when he declared "*the whole of the crew were drowned*." One of the two men who were not drowned, and who were in the boat at the time it was lowered, stated positively in evidence that "*the patent did not foul*." I may further add that the attention of Captain Lean, R.N., the chief emigration officer of the city of London, having been directed to this case (not by Messrs. Green, the parties interested), I have been given to understand the result of his inquiry was, that in this misfortune "no blame whatever was to be attributed to the apparatus."

My plan or any other can do no more than safely lower a boat on to the water, and this it did in the instance referred to, in a heavy snow-storm, with such a sea running that it was a source of wonder to those on board that the boat ever lived through it at all even when on the water, and when the officers of the ship generally admitted that any attempt to lower a boat ought not to have been made; and it is a sufficient testimony to the soundness of my system that after having been fitted in at least a *thousand boats* during the *last four years*, the only case of failure with a fatal result that can be set up against

it by opponents having other interests to serve is this miserable one of the Orwell.

That my plan stands alone in the proofs of practical utility it has shown by the number of lives saved I now repeat. Take, for instance, Her Majesty's Ships, Shannon (on two occasions), Raccoon, Chesapeake, and Perseverance; from steamers of the largest class, Australasian (on two occasions), Queen of the South, and Indiana; from sailing ships and other steamers, the Commodore Perry and Champion of the Seas (ships of nearly 2,000 tons each); the Washington Irving, Blundell, Black Eagle, Ebba Brahe, Omega, Medway, Queen, Transatlantic, Admiral Boxer, Grand Trianon, Lady Mc Naghten, Rodney, Duke of Rothsay, and several others I cannot now call to mind. From all these ships have lives been saved, and nearly always under circumstances of considerable difficulty, often in the severest gales, and almost universally from vessels under steam or canvas. In two of these cases the entire crews of the ships have been preserved by its instrumentality, and on several occasions more than one human being at the time. All these cases are vouched for by the officers of the different ships. At the memorable preservation of the steam troop ship "Sarah Sands" (when half consumed by fire) Captain Castle has publicly recorded its "perfect efficiency" in lowering the life-boats filled with the women and children, when he says that by "the ordinary method he would not have attempted such a thing;" and the captains of the Eastern City and Merchantman also bear their written testimony to a like result, when the former ship was entirely burnt. Only during the last few days two other cases have reached me, one from Her Majesty's ship "Archer," on the coast of Africa, about which an officer on board writes, a "few days since a man who fell overboard was saved from the sharks, thanks to Mr. Clifford's apparatus;" and the other from a Scotch steamer, in which the same gear has been in use for two years. The carpenter fell overboard from the sponson in the night, vessel under full steam, but was instantly picked up. The last case proves that time, as "Nauticus" states, has not been such an enemy to my system. Captain Morris, of the late "Eastern Monarch," only this week writes me also of a boat lowered for a like purpose under most trying circumstances with perfect success. It is not from arrogance I have mentioned these instances, but only in reply to one who uses that term for no other purpose than to injure me; and I have a right to ask if any equal list can be shown by any other inventor?

The imaginary parallel that "Nauticus" fabricates about the patent safety lamp for the purpose of detracting from the value of positive evidence that he cannot disprove, needs no answer from me.

It is not a fact, moreover, as he states, that "my desire for competitive trials was forestalled," for since I first turned my attention to this subject, eight years ago, I have urged upon the Government the public good that must result from such a course being taken by the proper authorities, and the right that every inventor had to a like opportunity of proving the efficiency of his system. I felt this the more strongly as for some time I was refused a trial by the Admiralty at my own expense; but which, like other inventors, I might have obtained if I had courted interest or patronage. But I have never sought advancement by such means, and I will not begin now. I have had no friend high in the service to open the door for me, or to sue in Parliament for a dignity or a recompense when the first life was saved by my gear. No one knows better than I do how seriously the want of professional standing adds to the uphill work of prosecuting such a cause as I have had in hand; and, however gratifying it may be to one of "Nauticus'" position to refer to "a person of an opposite calling," it is some testimony to the intrinsic value of my invention that, with this dead weight, it has reached its present position in the public estimation, and the different departments of the Government.

Boat-lowering safely in heavy weather is no theory; it is a hard matter of fact, and the difficulties to be surmounted purely mechanical, and he must evidently deserve the first place who can give the most practical proof of efficiency. While the fleet is in the Channel or off Spithead, let the Admiralty order a series of public trials to be instituted; not a casual lowering or two now and then under particular officers, who may happen to be relatives or personal friends of one of the competitors, but such a series as will afford a sure and certain proof of the relative qualities of any improved system, and let those be visible to the profession and the public.

In the heavy sea-way, and from the rolling or pitching ship, whether at anchor or under way, such things are most wanted, and it is under such positions they should be tried. If the Admiralty or "Nauticus" will endeavour to bring about this end, more national good will result than from columns on columns of argument; and when such an occasion is afforded, results will prove whose theories are mere theories, and whose deserve a higher appellation.

The way in which your pages have always been open to discussion on this important subject merits the warmest thanks of the seaman, and I trust that in your desire to steer clear of purely personal controversy which can never benefit a public cause, you will not hesitate to find space for any who strive to fix public attention on the present neglected state of boat lowering, but will yourself urge as you have heretofore the imperative necessity of the Admiralty's taking the lead (as it should do,) in the movement now happily going on, for benefitting the hard fate of those "whose lot is cast upon the waters," by ensuring for them the advantages of an efficient means of lowering the boats in every ship that puts to sea, and visiting with deserved punishment all who, having such means on board, neglect to keep it in proper working order, and available at the required moment. Whilst their lordships give every encouragement to any new means for the destruction of human life, surely they will make some effort to help its preservation, and let the seaman see that the better feelings of human nature find a place for him in the breasts of his superiors and officers, and that in the hour of need he will not now be left as heretofore to struggle and sink into eternity because official lethargy and indifference withheld the means that might have saved him.

Yours, &c.,

CHARLES CLIFFORD.

August 2, 1859.

ELECTRIC TELEGRAPH CABLES.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—May I beg the insertion of a few remarks on a letter which appeared in your journal of last week, from Messrs. Hall and Wells, on the subject of my telegraph cable.

It appears that my letters to them respecting their infringement of my patent, which were essentially of a private character, have induced them to adopt the strange course of attempting publicly to disparage my invention, and repudiate my claim. I hardly know whether Messrs. H. and W. are fishing for information upon the subject about which they confess they are "puzzled," or whether they have fallen into the error of imagining that I am not myself a practical man, and that I had not fully provided for all the little difficulties which to them at present appear insurmountable. I admit the fact, in my specification, that wires have been sometimes covered with fibrous substances previously to coating with the insulating material, but I deny that this process has ever been employed for the object patented by me. As for the portion of my patent, viz., the employment of porous or fibrous substances in conjunction with the insulating material, for which Messrs. H. and W. gave me credit, but of the practicability of which they seem to express doubts, although they are themselves actually infringing my patent by adopting a modification of the process, I can only tell them that the Gutta-percha Company will be ready when required to

manufacture cables upon my plan without the slightest difficulty; and if Messrs. H. and W. should ever think of carrying out my process to the extent contemplated by me, adopting india-rubber as the medium of insulation, I shall be very happy, with a proper understanding, to put them in the way of doing so, as there is not the slightest difficulty in the matter. Messrs. H. and W. profess to be practical men; I will not dispute this; but I am afraid that they are not equally good electricians; hence perhaps their reason for the expression, "we cannot follow Mr. Hearder through such a multiplicity of ideas as to the construction of a cable under his patent, as it would be simply a waste of time." I may inform Messrs. H. and W. that other manufacturers differ from them in opinion, and certain electricians and telegraph engineers whom I might mention, of the very highest authority, are unmeasured in their terms of approbation of the plan. Lastly, I may mention for Messrs. H. and W.'s information, that being myself a mechanical engineer as well as an electrician, I have appliances for constructing any description of machinery required for the purpose, or, if necessary, of constructing the cable itself, and I can show them machinery much on the same principle as that described in their specification, which I have had in operation for covering and counter-covering wire nearly 20 years.

I cannot imagine that Messrs. H. and W. can have read my specification attentively, or they certainly would not have ventured to dispute the novelty of every part of my process in its application to the intended purpose, viz., that of lessening the mischievous effects of induction.

I hope that my remarks will not be received as uncourteous; I have not the slightest desire to take any hostile position with regard to Messrs. H. and W., because from the samples of their cable with which they have favoured me, I can see plainly that much greater advantages would accrue from our co-operation, as my process can be carried out quite as efficiently with india-rubber as an insulator as with gutta-percha. The object which I have had in view has been to apply well recognised electrical principles to the improvement of telegraph cables, principally with a view of lessening the effects of inductive action, still also keeping in sight the attainment of desiderata which experience has shown to be necessary in the construction of new cables. One of my processes for accomplishing this object, is by embodying with the layers of insulating materials strands of suitable substances, twisted or braided, or laid on in any convenient and efficient way, and, if necessary, I braid or twist string over the whole cable, and render it waterproof.

My internal conductor, also, is made of dimensions suitable for affording the least resistance to the transmission of the current. I believe that no one acquainted with telegraph engineering will be prepared to deny that a cable carefully constructed upon this principle, would possess every quality that could be desired. It would be light, amazingly strong, as perfectly insulating as the best that have been made, and infinitely more free from the effects of induced residual discharges than any cable that has been, or can be made, upon any plan existing prior to my own. I am quite aware that the complete apprehension of the principles upon which my plan is founded, involves a rather more intimate acquaintance with electrical laws and phenomena than is possessed even by many "practical men;" but the careful consideration of them, however, by those competent to form an opinion, has resulted in the full recognition of the value and efficiency of my plan.

The specific gravity of this cable being very little greater than that of water, the simplest possible form of break would be sufficient to lay it, small weights being only necessary at intervals to facilitate its sinking when in deep water.

I remain, Gentlemen,

Your obedient servant,

J. N. HEARDER.

Plymouth, August 8, 1859.

THE COMMITTEE ON DOCKYARD ECONOMY AND EFFICIENCY.

H.M. Dockyard, Portsmouth, 8th Aug., 1859.

SIR,—Courtesy always permits a reply to a personal attack. The undue prominence you have given to my name with reference to the Report of the Committee on Dockyard Economy and Efficiency, requires that I should address you to disclaim that prominence, and to say that you have formed a very false estimate of the part taken by the other members of the Committee.

The Report may with much more justice be said to be based on the experience of Admiral Smart as Superintendent of Pembroke Yard—on the great and varied knowledge possessed by Mr. Laws respecting all branches of the Dockyards, obtained while serving as clerk in the Master Shipwright's Office, as Superintendent's Secretary, Store Receiver and Storekeeper—and on Mr. Bowman's knowledge and experience of the mode of conducting work in private shipbuilding and other establishments, in addition to the information obtained while serving on the Committee.

To your insinuations against my own character, I could easily reply, but knowing that your Editor Mr. Reed, who writes the ship-building articles in connexion with your journal, was a dockyard apprentice, and was educated within the last few years at the late Central Mathematical School under the system disapproved of in the Report, and his schoolfellows being employed in the Surveyor's office and in the Dockyards, I do not consider it necessary to do so, more especially as I feel that while your attempt to filch from us such good names as we may have will do your journal no good, it is not likely to do us or our Report much harm.

I am, Sirs, yours obediently,

ANDREW MURRAY.

To Messrs. Brooman & Reed, Joint Editors.

Law Case.

(Before Vice-Chancellor Sir R. T. Kindersley.)

THE DESICCATED MILK COMPANY (LIMITED) v. FADEUILHE.

This was a motion for an injunction to restrain the infringement of a patent for solidifying and preserving milk, under these circumstances:—It appeared that the plaintiff, Thomas Shipp Grimwade, took out a patent in 1855 for preserving and solidifying milk, which was effected by the following process:—The milk, being mixed with certain proportions of alkali and sugar, was then evaporated by being placed in a square tin tank with a chamber beneath, containing hot water, and constantly agitated by means of a crank and quadrant beneath, until the mass became of the consistence of dough. This dough was then dried into hard cakes, which were again crushed between powerful granite rollers and bottled, the bottles being closely stopped. It was then fit for use. The defendant, Valentine Bernard Fadeuilhe, was the assignee of a patent taken out in 1848 by Felix Hiacynthe Folliett Louis, whose process was of this kind:—Sugar and alkali being mixed with milk or with curd turned in the ordinary mode by runnet, it was placed in circular pans with false bottoms, communicating with three upright hollow standards, and a reservoir at the bottom, into which, by means of a valve, steam was introduced, and the liquid in each pan while evaporating was kept in agitation by means of a spindle passing through the centre of each with fluid-tight collars, to which spindle in each pan a rake was attached, the spindle being turned by a handle acting laterally upon a toothed wheel at the top of the spindle. The milk thus evaporated was formed into cakes, and the defendant, after a time, grated these cakes into powder and bottled it. This was in 1853, but subsequently to the date of the plaintiff's patent he admitted that he had dried the mass, but in ignorance of the fact that this method formed a part of the plaintiff's invention. The plaintiff, having discovered that the defendant was manufacturing and selling the article in bottles, drying it by a process similar to

his, which did not form a part of the patent of Louis, filed the present bill to restrain the alleged infringement of his patent. It appeared that the plaintiff's invention had been extensively used at Balaklava, and by Miss Nightingale during her attendance on the sick.

Mr. Glasse and Mr. Bristowe appeared in support of the motion. Mr. Baily and Mr. Cadman Jones, for the defendant, were not called upon.

The Vice-Chancellor observing that, as it might turn out and must be assumed that the plaintiff's patent might be invalid, unless there was a user and enjoyment for a long time, he ought not to grant an injunction. The motion must stand over, with liberty to the plaintiff to bring such action as he might be advised, an account being meantime kept.

Our Weekly Gossip.

The Atlantic Telegraph Company have issued the following invitation:—"All persons having any specimens or plans of submarine cables calculated for laying across the Atlantic are hereby invited to send the same to the Secretary of this Company, together with any description they may desire to append to them, as soon as possible, in order to their being immediately submitted to the officers of the Company, and by them to the consulting committee, for the purpose of examination, testing, and experiment."

Arrangements for the meeting of the British Association for the Advancement of Science at Aberdeen are proceeding. The Prince Consort has fixed on Wednesday the 14th of September for the delivery of his inaugural address. The following Vice-Presidents have been chosen:—The Duke of Richmond, the Earl of Aberdeen, the Lord Provost of Aberdeen, Sir John F. W. Herschel, Sir David Brewster, Sir R. I. Murchison, the Rev. W. V. Harcourt, the Rev. Dr. Robinson, and A. Thomas Esq.; Major-Gen. Sabino will act as General Secretary, and Prof. Phillips as Assistant General Secretary; the General Treasurer will be John Taylor, Esq., and the Secretaries for the meeting at Aberdeen, Profs. James Nicol and Frederick Fuller, and Mr. John F. White. Messrs. John Argus and Newell Burnett will act as Local Treasurers.

Sir William G. Armstrong has been good enough to confirm the doubt expressed in our last number respecting the *canard*, or as he calls it, the "wild goose story" of a contemporary. He says, "Whomade the wonderful shot that brought down a wild goose at six miles and seven furlongs? This is a question that meets me everywhere, and disagreeable though it be to spoil a marvellous story, I am obliged to answer—Nobody. A wild goose certainly was shot by a shell from one of my guns at a distance somewhat short of half a mile; and, although half a mile is not to be regarded as the limit of safe distance for a goose to stand at, yet I am bound to say that six miles and seven furlongs is a range which as yet has only been reached with the long-bow." Honours and emoluments have made Sir William jocular—on the principle, we presume, that he may laugh who wins.

In consequence of the continued favourable reports from the Captains and Commanders of ships whose boats are fitted with Captain Kynaston's life-hooks, the Admiralty have given directions to the several Dockyards, says the *United Service Gazette*, that they are, for the future, to be supplied to any Captain making application for them, without reference to the Admiralty. Captain Hillyar, of the *Cadmus*, has reported that during the voyage to Malta the boats had been lowered under every variety of wind and weather with perfect success. There is one very important feature in connection with this invention, which is the facility for applying the hooks to boats fitted on the old plan, in the course of a few minutes. They require no cumbersome machinery or windlass, and can be transferred from one boat to another without interfering with tackles or slings, while the cost of them is a mere trifle.

Mons. Barbedienne, of Paris, so well known for his bronzes d'art, and who received the highest medals for his works, both in 1851 and 1855, says, in writing to his correspondent in London, under the date of July 31st:—"Now that peace appears to become more firm every day, will it not be possible to return to your project for the exhibition of 1861? It appears to us that it is the duty of commerce and industry to rely with confidence on the interests of nations, and to discard all foolish and transient causes of antagonism and strife. In the actual state of things, a Great Exhibition in London would have a double

salutary effect, both in the industrial as well as in the political world. Personally, I will do everything in my power to promote so noble and excellent a cause."

A drinking fountain or two, for the splendid and extensive pleasure grounds for the people at Kew, is now, from the very great numbers flocking to them, very much required: till such a needful want is supplied, a delicious glass of pure spring water may be had (gratis), we are requested to state, by all visitors, of the official attendant in livery in charge of the lower room of the new museum, opposite the palm house in the botanic gardens.

Mr. Hearder, the well-known electrician and engineer, favours us with the following:—"Gentlemen,—In compliance with the wish of your correspondent, Mr. Chick, I have pleasure in explaining to him the cause of the result described by him in connection with his induction coil in your issue of July 29th, which to him appears so novel and curious. It simply indicates that his battery had not surface or rather quantity enough to fill, if I may use the expression, his thick No. 10½ primary coil. He will obtain still more exalted effects by making the number of plates in his second series equal to those of the first, which is equivalent to doubling the surface of each plate. Your correspondent does not say whether his graphite battery is a nitric acid one, or whether it is simply excited by sulphuric acid without a diaphragm, after the manner of Smee's. If the former, he will find that if he employs his series of 12 in a double set of six, or perhaps even better, in a triple set of four, he will get still finer effects. Twelve in series give him more intensity than his coil wants. Hoping that this will meet the wishes of your correspondent, I am, &c., J. N. HEARDER. Plymouth, Aug. 6, 1859."

Some Sheffield correspondents send us the following:—"It is allowed by all parties that the defences of this country against foreign aggression are in a very unsatisfactory and undesirable state. But we think they may be put in a more safe one at a comparatively small cost. We have to propose that a sufficient number of iron vessels made shot and fire-proof rams, built to strike the enemy's vessel under the water line, and to be built as low as possible above the water line, so as to be lower than the enemy's fire, to be of the greatest speed. These vessels to be armed with powerful fire-engines to throw liquid inflammables (such as coal, naphtha, turpentine, mixed with coal, tar, and phosphorus, &c.) into and upon the enemy, which may be done in hundreds of jets through small port-holes. By this means, in less time than it takes to write this sentence, the enemy might be enveloped in one entire sheet of flame. These fire-ships to be stationed at the entrance of rivers and harbours. We think they would deter an enemy from attempting to enter, as we think they could not escape destruction either from the ram or the inflammables. If these fire-ships were generally made use of, it would be more than useless to build any more wooden ships of war; it would be a complete waste of money, time, labour, and materials."

The most recent improvements in arms have been adopted, says the *Times* correspondent, by the Prussian Government. The needle gun with which the army is furnished is known in England as the rival of the Enfield, and many consider that it is less liable to get out of order. The merits of the two systems have not yet had a sufficient trial to enable a final judgment to be formed. The artillery already possesses 72 rifled 12-pounders of remarkable lightness. They are of cast-steel, and breech-loaders. In the experiments which have been made the guns were found uninjured after firing 2,000 rounds. Their manufacture is being pushed on with vigour, and they are turned out at the rate of one gun in two days. It is intended that there shall be in each field battery a proportion of unrifled 12-pounders, as the new guns have not been found adapted for firing grape. They have no such destructive missile as the Armstrong shell is described to be. This is the practical way in which Prussia is imitating the example of disarmament.

NOTICES.

The MECHANICS' MAGAZINE will be sent free by post to all subscribers of £1 1s. 8d., annually, payable in advance. Post Office Orders to be made payable to R. A. Brooman, at the Post Office, Fleet Street, London, E.C.

TO ADVERTISERS.

All Advertisements occupying less than half-a-column are charged at the rate of 5d. per line for any number of insertions less than 13; for 13 insertions, 4d. per line; and for 52 insertions, 3d. per line.

Each line consists of 10 words, the first line counting as two. Wood-cuts are charged at the same rate as type for the space occupied.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgement:—

STEAM ENGINES, &c., 2952, 2962.

BOILERS AND THEIR FURNACES, 2922, 2955, 2962.

ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 2919, 2948, 2950, 2963, 2970.

SHIPS AND BOATS, including their fittings, 2908, 2914, 2928.

CULTIVATION OF THE SOIL, including agricultural and horticultural implements and machines, 2925, 2964, 2977.

FOOD AND BEVERAGES, including apparatus for preparing food for men and animals. *None.*

FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 2910, 2912, 2915, 2917, 2923, 2932, 2933, 2934, 2941, 2942, 2945, 2946, 2969, 2972, 2974, 2976.

BUILDINGS AND BUILDING MATERIALS, including sewers, drain-pipes, brick and tile machines, &c., 2924.

LIGHTING, HEATING, AND VENTILATING, 2911, 2949, 2953, 2960, 2975.

FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 2927, 2931, 2954, 2965, 2971.

METALS, including apparatus for their manufacture, 2921, 2935.

CHEMISTRY AND PHOTOGRAPHY, 2961.

ELECTRICAL APPARATUS, 2937.

WARFARE, 2938.

LETTER PRESSES PRINTING &c. *None.*

MISCELLANEOUS, 2907, 2909, 2912, 2913, 2916, 2918, 2920, 2926, 2929, 2930, 2936, 2937, 2939, 2943, 2944, 2947, 2951, 2952, 2953, 2956, 2957, 2958, 2959, 2966, 2967, 2968, 2973.

2907. T. S. WOODCOCK. "An improved index or book and paper marker." (A communication.) Dated Dec. 20, 1858.

Here the clasp is of any convenient size, and made of one piece of metal with the angle between its points for receiving the leaf while the clasp is applied in a vertical position or nearly so, and opening to receive the leaf as it is pressed against its edge, and firmly grasping the leaf. *Patent completed.*

2908. S. HUNTER. "Improvements in the construction of anchors." Dated Dec. 20, 1858.

This relates to the arms and palms of anchors, and consists in enclosing the palm at the end of the arm, and making the arm open up to the point of junction with the shank, for which purpose the arm is divided into two parts, whereby the earth in front of the palm or fluke is not crushed or divided by the arm during the dragging of the anchor, but passes through the arm and over the upper edge of the palm in a comparatively compact and solid state, thereby greatly increasing the hold of the anchor by creating a more perfect downward pressure. *Patent completed.*

2909. R. MACLEHOUSE. "Improvements in stereoscopes." Dated Dec. 20, 1858.

This apparatus is in the form of a deep rectangular box fitted at one end near the top with the usual stereoscopic glasses. In the line of sight and between the glasses and the extreme back of the box or case, there is placed an open drum or roller having four or other convenient number of sides. This open drum is arranged to work upon a horizontal spindle to which is attached a projecting handle for turning it by. Behind this drum and in the end of the case there is a hinged door folding downwards, and fitted with a mirror for throwing light into the interior of the case. The pictures are disposed in the chain form over the drum, and so arranged that one end of the chain can fall down into the bottom of the case at the front, and the other at the back portion of the case. With this arrangement as the drum is turned, the pictures are successively drawn up from the back section of the bottom of the case, passed over the faces of the drum on the vertical side of which for the time being they are successively displaced, and then passed down in a zig-zag or regularly folded pile in the bottom of the front portion of the case. The open form of picture drums with the door behind admit of transparencies being viewed in this apparatus. *Patent abandoned.*

2910. J. RONALD. "An improved machine for the direct spinning of hemp, flax, and other like fibrous materials." Dated Dec. 20, 1858.

This machine is constructed of a horizontal endless band or chain, or by preference a pair of horizontal endless bands or chains placed one above another,

and on which are mounted a number of gill teeth, the upper and lower teeth of which intersect each other. These endless chains are stretched between two pairs of drawing rolls and work upon pulleys at each end. The machine is so arranged that the gill teeth travel a little faster than the periphery of the first pair of drawing rolls, and the second pair of drawing rolls are driven a little faster than the gill teeth, so that there may always be a drawing action on the fibres during their passage through the machine. *Patent completed.*

2911. A. V. NEWTON. "An improvement in lanterns." (A communication.) Dated Dec. 20, 1858.

The object here is to obtain by simple means a combination of reflecting surfaces with or without a lens that will project the rays of light from a lamp into space in a concentrated form, and in parallel lines. The invention consists mainly in the employment of a peculiar arrangement of conical and convex reflector, which form a chamber for the reception of the lamp, and also effects the object above alluded to. *Patent abandoned.*

2912. F. WINTER. "Improvements in the preparation and application of varnishes for waterproofing paper, linen, and textile fabrics, and coating the same with metallic foils." Dated Dec. 21, 1858.

This varnish may be composed of shell-lac, benzoin, and Venice turpentine dissolved in spirits of wine and wood naphtha. Other combinations are included. *Patent abandoned.*

2913. R. M. LIVINGSTON. "An improved self-detaching safety hook or coupling." Dated Dec. 21, 1858.

Instantly on the suspended boat or other weight coming into contact with water or otherwise, and the small chain being disengaged from one of the lever ends, their weighted ends will cause the lower or hooked ends to open. *Patent abandoned.*

2914. W. E. DANDO. "Improvements in apparatus for lowering boats from ships or vessels, and also for raising the same as required." Dated Dec. 21, 1858.

This invention is not described apart from the drawings. *Patent completed.*

2915. J. H. BOLTON and C. GARFORTH. "Certain improvements in drying yarns or fabrics, and in the apparatus connected therewith." Dated Dec. 21, 1858.

The sizing vat or vessel is furnished with a series of rollers, so arranged that the yarn or fabric may pass over a sufficient number of them, and remain in the size until saturated. It then passes out of the vat between a pair of squeezing or pressing rollers, and becomes partially dried; it is then again passed through the size, and finally between pressing and delivery rollers into a chamber containing near its base a number of vertical arched or bent plates arranged in pairs and forming chambers, and having a series of rollers, so arranged that the yarn or fabric may first pass under or between or in the interior of these arched plates or chambers to be partially dried, and thence along the outside of the plates and over rollers at the top of the outer vertical chamber or room in which all are enclosed where the drying is completed; the yarn passes out of this chamber in a dry and finished state, such chamber plates being heated by steam. *Patent abandoned.*

2916. A. S. BELLIARD. "An improved machine for pumicing felts, tissues, and skins." Dated Dec. 21, 1858.

Here the felt is submitted to what may be called a grinding operation by a small mill or grindstone of pumice stone, which is caused to revolve by mechanical means, and is pressed by hand upon other felt. *Patent completed.*

2917. W. S. YATES. "Machinery or apparatus for dragging bristles and drawing hair and vegetable fibre." Dated Dec. 21, 1858.

The inventor employs gill combs and presses between which the bristles, hair, or fibre is placed and held to be operated on and nippers or jaws capable of closing and opening by the action of tappets or cams, and also having a receding and advancing or reciprocating motion given thereto, so as to advance and take hold of the projecting ends of bristles, hair, or fibre and draw them out from the rest, and which by the opening of the said nippers when out, are deposited in a receptacle. *Patent completed.*

2918. N. DAWSON. "Improvements in order books." Dated Dec. 21, 1858.

This consists in binding up a number of leaves, every alternate one of which is perforated so that it may be readily torn out of the book while the others remain in the book. While taking orders on these perforated leaves a piece of carbonized paper is placed between it and the next leaf, so that an exact counterpart of the order will be obtained. *Patent abandoned.*

2919. W. MAINWARING. "Improvements in brakes for common road vehicles." Dated Dec. 21, 1858.

This relates to brakes for two-wheeled vehicles to relieve the horses attached thereto when going down hill. On the axle-tree is attached a rigid pendant arm or arms the lower part of which supports the fulcrum of a long lever the fore-end of which carries a skid or brake surface which when lowered rubs against the ground; this end of the lever projects forward in front of the wheels while the back and free end by which the brake is actuated projects behind the cart, &c., so that the driver may readily apply it. This end of the lever is furnished with an arc and stop pin by which to fix the lever in the different positions desired. *Patent abandoned.*

2920. R. CLEGG, F. ANGERSTEIN, and G. FERRY. "Improved mechanism for imparting reciprocating motion to machinery, and more especially pumps." Dated Dec. 22, 1858.

The inventors propose to so construct a cam, as that about three-fourths of its entire revolution shall be effectively employed for lifting, and the other fourth for the descent of the bucket; or instead of lifting and descending only once during each revolution of the said cam, the same may be made to lift and descend twice in each entire revolution thereof, or more times if desired according to the size of the cams. *Patent completed.*

2921. R. MURPHY. "An improvement or improvements in the manufacture of cast steel." Dated Dec. 22, 1858.

This consists in manufacturing cast-steel by melting together, or combining when melted, the following materials, that is to say, broken or crusted or granulated cast-iron, whether cast-iron, whether pig-iron, or refined metal, deoxidized iron ore or oxide of iron, and a metallic compound consisting of or containing iron carbon and manganese. The said materials are melted in melting pots or crucibles heated in furnaces of the kind ordinarily employed for melting steel. *Patent completed.*

2922. G. SHARP and W. EIDER. "Improvements in furnaces and steam-boilers." Dated Dec. 22, 1858.

The inventors supply fuel to the furnace at the speed and time required by a screw placed outside of a hollow barrel or cylinder through the interior of which the necessary air passes to the furnace. The air enters through a nozzle or other suitable arrangement, and the fuel through a hole or other contrivance. Upon the exterior of the barrel are placed feathers or arms for spreading the coal and forcing the air into the interior of the furnace. *Patent abandoned.*

2923. J. NICHOLSON and D. CROSSLBY. "Improvements in jacquard machinery or apparatus employed in weaving." Dated Dec. 23, 1858.

The object here is the weaving of all kinds of double, triple, and two-faced or reversible cloths plain or twilled, by hand or power without the use of heddles, gear, movable harness boards, or having to stamp the ground on the pattern cards, by jacquard machinery or apparatus so constructed and arranged that it can be operated by a single treadle on the treadling tappet of the loom. The inventors employ lifting bars which receive reciprocating motion from the treadle or treadling tappet by a lever and connecting rod, also a series of grifes or lifting boards with knotted tabby bands for working both the figure and the ground, which are raised by hooked rods hinged so as to be capable of connecting the boards with the lifting bars at the proper time required, and which is indicated by cams suitably arranged on a shaft or shafts which receive intermittent motion from the motion of the lifting bars. The pattern cylinders receive intermittent motion from the lifting apparatus at the first, second, or third lift of the machine, according to the kind of cloths required to be made, and it is so arranged that it may be turned without moving the loom. *Patent abandoned.*

2924. M. REXNEY. "Improvements in bridges." Dated Dec. 22, 1858.

This relates to bridges usually designated sliding or rolling bridges, which are substituted for swing or swivel bridges, and consists in so constructing a rolling bridge that it shall be perfectly balanced and require but little power to open and close it, and that whilst it is closed, and in use, it is perfectly secure, and the road and approaches are made as it were continuous and unbroken, and when opened or withdrawn the tail or balance end is drawn over the ground line or approach on the balance or withdrawing side, and without injury thereto. The travelling of the bridge in and out may be effected by a rack or racks or otherwise. *Patent completed.*

2925. W. SPENCE. "Improvements in granaries or apparatus for preserving grain." (A communication.) Dated Dec. 22, 1858.

This consists of a strong chest composed of wood or other material adapted to give it strength supported on pillars or standards and strengthened by cross tie pieces bound together by clamps, being also kept from yielding to the pressure in an outward direction by longitudinal and lateral stretchers. The bottom of the said chest terminates in a funnel or hopper, and at its extremity is fitted a pipe or conduit, furnished with a valve or regulator, which is closed by a padlock when the apparatus is at rest. This pipe or conduit, which serves equally for putting grain into sacks, leads to a sieve of ordinary form and furnished with a handle or means of turning it on each side. To the sieve is connected an inclined board or channel receiving a jerking kind of movement from the sieve, and which conducts the grain from the latter to a receptacle either under or above ground, which receptacle is closed by a door. Into this receptacle an endless bucket chain dips, being passed over a pulley at the lower part of the receptacle, and over another mounted at the upper part of the apparatus. On the axle of the former pulley is another of larger diameter, which by means of an endless strap or band communicates the motion of the chain to the sieve when the apparatus is driven by mechanical power, but when manual labour is employed motion is communicated from the sieve to the chain. The chain receives its motion from the prime mover through a driving pulley. At the upper part of the apparatus is a receptacle for the grain as it is carried up and deposited by the working of the chain, such receptacle communicating with the apparatus through a grating to prevent mice, &c., from passing into the same. Access is afforded to the upper part of the apparatus by a staircase or otherwise, and there is a railing to prevent accidents. There is also an indicator consisting of a ball suspended by a cord or chain, to which is also connected a kind of parachute with moveable wings. As the grain has become ventilated or winnowed the ball descends to obstruct the passage of it to the sieve, and when the contents of the granary or apparatus have been operated upon, the outlet is closed, and the ball is drawn up again, the wings of the parachute collapsing as it passes through the mass of grain. There is also a graduated index intended to show the quantity of grain which the granary or apparatus contains. *Patent completed.*

2926. E. T. DUNN. "Improved fabrics suitable for the covering of floors, walls, and other like purposes." Dated Dec. 22, 1858.

This invention was described at page 62, No. 4, of the MECHANICS' MAGAZINE (New Series). *Patent completed.*

2927. E. GREEN. "Improvements in tables." Dated Dec. 22, 1858.

This consists in forming tables with a central revolving disc, which is fixed within or placed upon the centre of a table. Or in constructing tables with two or more discs, each having a separate motion to enable them to move in the same or in a reverse direction. It also consists in fitting suitable gear to the tables, so that the discs on one or more of them may be rotated by turning a handle or treadle. *Patent abandoned.*

2928. M. SHULDHAM. "Improvements in ships and vessels, and in working parts of their gear and rigging." Dated Dec. 22, 1858.

This consists in methods of running in or hoisting up a ship's bowsprit, with its jib-boom and flying-jib-boom, so as to enable a ship, constructed as a steam ram, to carry sufficient head-sails, and notwithstanding to be in a fit state to perform the duty of a steam ram. *Patent abandoned.*

2929. F. RANSOME. "Improvements in the manufacture of grinding and rubbing surfaces." Dated Dec. 22, 1858.

This consists in combining ground glass or emery with soluble or easily fusible silicates with or without other matters. *Patent completed.*

2930. A. PRINCE. "Improvements in ornamenting and illuminating surfaces of glass." Dated Dec. 22, 1858.

This consists in the application of lace or flower pattern glass having clear plain centres or spaces, such centres or spaces being encircled or delineated by ornamental plain or coloured bordering, so as to form an interval frame pattern, and in and upon such colour centres or spaces chromolithograph or other impressions prints or paintings are transferred, attached, or painted, and then coated and covered with suitable crystal cements and varnishes as a protection against damage from atmospheric influence or moisture. *Patent completed.*

2931. J. J. WELCH. "Improvements in the manufacture of neckties, scarfs, or cravats." Dated Dec. 22, 1858.

This consists in letting in, inserting, or attaching

ornamental ends or tips to the ends of neckties, scarfs, or cravats, and such ornamental ends may be so attached by the aid of the sewing machine or by hand work. *Patent abandoned.*

2932. D. LICHTENSTADT. "Converting a certain vegetable substance into fibrous material for the manufacture of textile and other fabrics." Dated Dec. 23, 1858.

This consists in utilizing the sugar cane deprived of its sugar by reducing that vegetable substance to fibrous material which may be spun, woven, and otherwise treated so as to produce textile and other fabrics. *Patent abandoned.*

2933. J. RONALD. "Improvements in, and machinery for, the manufacture of hard-topped and soft-laid twine, mill banding, strands for ropes and other purposes, and cordage generally from hemp, flax, cotton, and other like fibrous material." Dated Dec. 23, 1858.

This consists of a number of revolving spindles or frames, each of which carries one or more bobbins on which the yarn is wound. The inventor gives an independent rotary motion to each of these spindles or frames by which any required amount of twist can be put into each yarn as it is drawn off the bobbin or bobbins, which is effected by a series of drawing rollers. The yarns required to form the twine or cord are conducted to sets of drawing rollers through draw-plates or other guides, and after the yarns have passed through several sets of these drawing rollers the hard yarns are then carried vertically down to a flyer by which they are laid, and as the cord is formed it is taken up by the bobbins on the flyer spindles. To spin twine, &c., direct from fibres of hemp, flax, manilla, &c., the inventor gives a rotary motion to the cams containing the sliders by mounting them on or insuitably formed revolving frames fitted with drawing heads. The twist being put into the sliver, and the yarn formed by the revolving drawing head, is carried forward by a series of the drawing rollers as before described, when the yarns are laid by flyers, and the strands as formed are taken up on bobbins on the flyer spindles. To form laid rope or cordage all that is required is to supply the bobbins with strands in place of yarn. *Patent completed.*

2934. S. BIRD. "Improvements in spinning, and in the manufacture of cop bottoms or cop tubes." Dated Dec. 23, 1858.

Here, to prevent waste after the cops are taken off the spindles the inventor applies gum, starch, paste, or varnish, or mixture of chalk, whiting, or flour, either to the spindles or to the threads by a brush or sponge so that when the spinning commences the threads shall be lapped to any desired thickness on to the sticking or thickening substance, which latter becomes hard before the cop is completed, so that the cop can be taken off without injuring the bottom, and which also prevents any unravelling or waste from picking. There are modifications included. *Patent abandoned.*

2935. J. BROOM. "Improvements in the manufacture of steel." Dated Dec. 23, 1858.

Here pig iron is deposited in its raw unheated state in the furnace, and it is worked and puddled in the usual way except that the furnace is kept as full as possible of pure white flame, the atmospheric air being excluded from it as much as possible. The mass of iron is also kept surrounded with cinder as a protective covering to keep off the contact of air with the metal. Sal ammoniac or salt may be added to improve the protective covering of cinders. The iron so puddled when tilted, hammered, or rolled becomes good steel. *Patent abandoned.*

2936. J. WHITEHEAD. "Improvements in sewerage and drainage apparatus." Dated Dec. 23, 1858.

In arranging receiving and discharging apparatus according to this invention the trap or sewer and drain chamber is so contrived that the fluid matters discharged from the road or street are caused to flow into the receiver through a hinged grating into the body of the trap-chamber. From this part the matters flow off beneath a hanging diaphragm, thence passing off at the other side over the top of a second diaphragm or division, and thence down to the main sewer or discharge duct. This diaphragm portion of the chamber is covered by a perforated plate of metal on which is disposed a layer of charcoal, lime, or gypsum, which layer is again covered in by an adjustable top plate level with the surface of the road. The roof-water from the houses is conducted into the chamber at the part between the two diaphragms so as to discharge the water in the same way as the street-surface water. Another branch also from the water pipe leads into the space containing the deodorizing matter. This branch serves to allow of the free escape of the gases from the chamber after passing through the deodorizing matter so as to pass right up the water-conducting

pipes to the top of the house. In this way so long as much rain water is discharged into the trap chamber the gases are carried directly off down the drains, but when the water pipes are empty the deodorized gases are passed off high into the air without doing injury. *Patent completed.*

2937. A. BARCLAY. "Improvements in obtaining and distributing or applying electricity and magnetism, and obtaining motive power therefrom." Dated Dec. 23, 1858.

This consists in a means of obtaining electricity from the earth in great quantity, and in distributing it and applying it either in quantity or intensity to practical use. According to one modification the receiving end of a conducting wire or series of wires is connected to a vertical or other line of parallel wires laid together, and which line forms the centre of a series of transverse or radial aries. These wires are so attached to the main central line that the arrangement resembles a "bottle brush," presenting a vast number of radial points for the collection and reception of electricity. This collector is sunk in the earth, so that each wire point takes up a portion of electricity and the points as a whole convey the electricity to the main central line of wire, and thence to the line-wire or conductor, which may be a telegraph cable or a conductor to an electric power machine. Or the apparatus may be immersed in a well containing a solution of sulphate of copper. Instead of radial wires metal discs may be used. In the case of a telegraph cable one of these arrangements is fitted up at each end, one being the collector and the other the distributor of the electricity. The invention also relates to an apparatus operating generally upon the galvanometrical principle, and capable of use for telegraphic purposes and for obtaining motive power. The details of this part of the invention are voluminous. *Patent completed.*

2938. J. MAUDSLAY. "Improvements in the construction of ordnance and projectiles to be used therewith." Dated Dec. 23, 1858.

This consists in the construction of ordnance and projectiles in such manner as to combine means of loading at the breech with a rifled bore and corresponding projectile. The breech chamber which is to contain the charge of powder is to be formed by preference of wrought-iron or steel, while the remainder of the gun is to be formed of cast metal. The shot, shell, &c., is to have formed on it a key or keys, feather or feathers for the greater part of its length, and the gun has formed in it a corresponding groove into which the key or feather on the projectile takes, and along which it moves. The thickness of the gun is increased about the groove in order to provide for the weakening effect which the formation of the groove would otherwise produce. The shifting breech is to have a lateral motion imparted to it bodily, and sufficient in extent to permit of the projectile being placed in its proper position in the gun. The breech is then brought back to its place by any convenient means, and there secured by a screw or otherwise. *Patent abandoned.*

2939. J. T. P. NEWBORN, T. SMITH, and J. BROWN. "Improvements in machinery or apparatus for raising and lowering, or otherwise moving heavy weights." Dated Dec. 24, 1858.

This relates, 1. to the combination of grooved drums, pulleys, or barrels as described with worm and wheel gearing. 2. To a novel contrivance for compressing the links of chains after they have been hauled in. The invention is not described apart from the drawings. *Patent completed.*

2940. W. ELLERS and L. FINK. "The filtration of dissolved sugar and other liquids." Dated Dec. 24, 1858.

This consists of a vessel with two bottoms, the upper one perforated with holes to which is attached the bag or filter. The two bottoms are placed apart from each other, thereby forming a chamber into which the liquor is introduced by a pipe from a higher level, which liquor rises through the holes into the bag or filter, and when filtered escapes by a pipe above the chamber between the two bottoms while the refuse remains in the chamber, or may fall into another chamber placed below it, from whence through an aperture the refuse can be removed and the chamber cleansed without disturbing the bag or filter. *Patent abandoned.*

2941. J. W. CHILD. "Improvements in the manufacture of fabrics adapted to be used for curtains, coverings of furniture, tables, covers, and such like uses." Dated Dec. 24, 1858.

The object here is to produce fabrics of a character now generally called "rep," or ribbed, and adapted to be used for curtains, coverings for furniture, &c., with pattern in various forms alike on each surface, combined with a ground work composed of ribs of

equal or unequal thickness, and such pattern or figure may be obtained on each side of the fabric from either the warp or the weft. When the pattern is to be obtained from the warp, such warp will be operated by the Jacquard, or otherwise, to obtain a like floating or satin pattern of the figures therefrom; and at the same time on each surface of the fabric, and to produce the different sizes of ribs, weft-threads of different thicknesses or quantities are employed. When the pattern is to be obtained from the weft, the operations will be conducted so as to obtain like floating of weft threads in place of warp on each surface of the fabric. *Patent completed.*

2942. J. W. CHILD. "Improvements in dyeing wool and other fibres." Dated Dec. 24, 1858.

This consists in dyeing wool, &c., when formed into a connected sliver by drawing such fibre in a continuous line in a distended state through the dye liquid, and thence to suitable washing and drying means, from which it is formed into balls or other forms. *Patent completed.*

2943. L. D. OWEN. "Improvements in manufacturing horse-shoe nails." (A communication.) Dated Dec. 24, 1858.

This consists of apparatus having suitable framework, with a shaft of proper strength and material hung thereon. On this shaft is an eccentric, which may be made self-adjusting, and to such eccentric the inventor attaches a chilled roller; on each revolution of the shaft the roller is made to strike the nail, rod, or iron a drawing or sliding blow from the head towards the point. The nail-rod having been passed in a red hot state between the two dies, and before the roller has made another revolution to give another such blow. One of the dies which is moveable is, by an eccentric or cam, caused to strike such nail sideways or horizontally, the other die which is fixed acting as a block or anvil. The shaft may be arranged to move forwards and backwards or to be stationary. The nail-rod is made to pass through a holder which has a kind of jigger motion to prevent scales forming on the nail-rod, and the inventor gauges the required length of nail-rod by a spring connected with such holder; the holder and nail-rod are then drawn back by cams, and when the nail is formed it is cut off and finished at each end if necessary. *Patent abandoned.*

2944. E. FELLOWS. "An improved vent peg." Dated Dec. 24, 1858.

This consists of a metal peg or stopper made of a taper form with a screw upon it. *Patent completed.*

2945. D. EDLESTON. "Improvements in preparing and finishing textile fabrics, and in the means or apparatus employed therein." Dated Dec. 24, 1858.

This consists, 1, in folding the fabrics in the wet state, whereby a better "rigg" in the finish is obtained. 2, in crabbing by series of cylinders arranged and constructed so as to have an increase of surface speed either by increase of diameters respectively, or in the relative times of rotation, such cylinders being immersed in hot water. 3 in the adaptation of such cylinders to the drying of textile fabrics by having them made hollow, drawing away the hot water and introducing steam to the interior thereof. 4 in combining the folding or rigging with the drying in one process by passing the fabric at its middle over the edge of a pulley or curved plate in a suitable position, by which the folding is effected and the fabric is then passed to the drying cylinder in the folded state. *Patent completed.*

2946. J. RAILTON and S. LANG. "Improvements in looms." Dated Dec. 24, 1858.

This relates to looms in which a double "dobby" is used for working the heads, and the invention consists in the application of a single slide to work the double "dobby," which slide is moved to and fro horizontally by a toothed wheel or pinion gearing into a rack fixed to or forming part of the slide. The pattern cylinders are turned round by catches jointed to a lever put in motion by the slide. The pegs on the pattern cylinders, or on the lattices passing over them, act on wires or tumblers connected to the slide, and these wires or tumblers are hooked to catch hold of knives or hooked rods to which the heads are connected by cranks or cords passing over pulleys. *Patent completed.*

2947. E. HEMPHEYS. "Improvements in brazing metal tubes in tube-plates and other metal surfaces to each other." Dated Dec. 24, 1858.

This consists in employing fluid metal in order to apply the requisite heat to melt the solder. *Patent abandoned.*

2948. A. SMITH. "Improvements in gigs, dog-carts, and other vehicles." Dated Dec. 24, 1858.

This consists in the application of a spring resting upon a lever, affixed in or to the frame work of the

front part of the vehicle. The lever is connected with a plain or other wheel having two circumferences inserted in the nave of one of the wheels of the vehicle, and the draught regulated thereupon by the action of a self-acting and self-regulating lever moving either backwards or forwards, according to the weight affecting the same. Motion being given to a pair of wheels connected with a self-acting and self-regulating screw attached to the body of any such vehicle, the draught on such vehicle resting upon three wheels on either side, inserted in the frame work of the vehicle, will be regulated and adjusted, and the body or framework may be drawn by the screw either backward or forward. *Patent abandoned.*

2949. J. LITTLE. "Improvements in lamps." Dated Dec. 24, 1858.

This consists of a central oil reservoir suspended from a rod attached to the ceiling or carried by a pedestal. From this central reservoir branches extend laterally for carrying the burners. Each branch terminates in a widened upward bend, to act as a chamber for containing the wick as well as to receive the oil in quantity sufficient to saturate the wick from the central reservoir. On the top of this branch chamber, there is screwed a wick-holder of any form with a pinion or other elevator. Upon this wick-holder there is fitted the actual burner, consisting of a top cap-piece perforated at the sides to admit air to pass in to aid combustion. *Patent abandoned.*

2950. J. H. JOHNSON. "Improvements in the permanent way of railways." (A communication.) Dated Dec. 24, 1858.

This consists in cutting notches or slots in the webs or shanks of the rails at their ends, and in inserting into such notches or slots wrought or cast iron joint-pieces of such a section as to enable them to fit accurately into the slots, and at the same time to fit against the sides or under the head of the rails at the ends thereof. To afford facility for taking up the rails certain of the rails, say every tenth rail, should have the slot made of extra length, so as to admit of the joint piece being slid along such slot, and consequently unlocked from the adjoining rail end, when the unlocked rail may be taken up. At these parts the joint-pieces may be retained in their places when locked by wooden wedge pieces driven behind them into the slot, and secured therein by a pin. *Patent completed.*

2951. R. L. GIANDONATI. "Improvements in ornamenting leather cloth." Dated Dec. 24, 1858.

This consists in ornamenting leather cloth by printing ornamental designs thereon, either in colours, or in metallic powders, or foil, without any further manipulation or treatment. *Patent abandoned.*

2952. W. B. JOHNSON. "Improvements in the employment of gas for generating steam, and in engines connected therewith." Dated Dec. 24, 1858.

This consists in certain methods of regulating the combustion of gas accordingly as more or less heat is required to be imparted to the boiler. For this purpose the inventor employs the governor of the engine, and causes it to act upon cocks or other such apparatus, so as to regulate the flow of gas. Also for the like purpose he causes the pressure or the temperature of the steam or water to act similarly to the governor. The invention also relates to the prevention of accidents arising from the water becoming deficient. In such cases he causes the supply of gas to be shut off or diminished by the water falling below a certain level. The invention further consists in the application of a "master light," for regulating the burners after the supply has been shut off and reopened. There is also an arrangement of engines and boilers to be used in conjunction with boilers heated by gas. The boiler is formed as a vertical cylinder of cast iron, with a concave bottom of copper. To the side of this the cylinder is bolted, and the main shaft passes transversely over the boiler, carrying the fly-wheel upon the opposite side of the cylinder. *Patent completed.*

2953. M. A. F. MENNONS. "An improved composition for the protection of certain metallic surfaces." (A communication.) Dated Dec. 27, 1858.

This consists in a combination of certain organic and inorganic substances which, introduced into boilers, &c., prevents the deposit or incrustation. The following ingredients are employed in the preparation of 100 lbs. weight of this compound:—Oak bark, 2½ lb.; salts of soda, 31 lb.; wood ash, 15 lb.; soda crystals, 2½ lb.; ground linseed, 4 lb.; graphite, 1 lb. These substances being reduced to powder, and thoroughly incorporated, are laid aside in a dry place. When required for use, a given quantity is reduced to a semi-liquid consistence by hot water, to which is added about 2 lb. per cent. of tallow. The mixture is then passed into the generator in the pro-

portion of about ¼ oz. (avoirdupois) of the powder per hour for each horse power. *Patent completed.*

2954. J. RADLEY. "An improved cooking apparatus." Dated Dec. 27, 1858.

This apparatus is adapted to the operations of roasting, boiling, baking, stewing, frying, and steaming, and all these operations can be carried on at the same time with one moderate-sized fire, and with little attendance. A modification of the apparatus may be readily adapted to travel on wheels, in order to cook for an army on the march; it carries its own fuel and water, and in this case the rotary motion for the roasting cage may be derived from the wheels. *Patent completed.*

2955. T. STREVER and T. SCOTT. "Improvements in heating apparatus for culinary and warming purposes, and in part applicable to steam boiler and other furnaces." Dated Dec. 27, 1858.

In a cooking range embodying some of these improvements the air is admitted through oblique openings in a door or frame, such openings being formed by using Venetian or oblique bars, fixed or adjustable as regards their positions. The object is to cause the air to enter so as to thoroughly mix with the fuel gases, and lessen the formation of smoke. In making a boiler for a cooking range, or for causing the circulation of hot water in pipes for heating apartments, it is preferred to form the bottom with corrugations. The boiler is formed with flanges, either solid or hollow, so as to constitute water spaces. If the cooking range is of the close fire class an independent flue or pipe is carried from it a sufficient distance up the chimney of the kitchen to obtain the requisite draught, without closing up the throat of the chimney or applying valves to it. The flue pipe has a valve to regulate the draught. When cooking is suspended, the apparatus is converted into an open fire-range by opening the fire-door and cover. The invention also comprises various improvements in stoves of the Register or Lenington class. *Patent completed.*

2956. J. SMETHURST. "Certain improvements in metallic pistons." Dated Dec. 27, 1858.

The object here is to render metallic pistons more elastic and easier of adjustment than heretofore. The inventor makes use of two packing rings, the inner circumferences of which are bevelled to fit a wedge ring, which is cut through in one place, or made in two or more parts, and is acted upon by an eccentric spring ring. The spring ring is made of cast-iron, and is cut through at one part. The spring ring must first be turned rather more in diameter than the internal diameter of the wedge ring or segments to give the requisite elasticity. These pistons can be used either with or without adjusting screws to act on the wedge ring or segments. *Patent completed.*

2957. J. SHAW. "A new mechanical combination, called an indefinite feed movement." Dated Dec. 27, 1858.

This invention is not described apart from the drawings. *Patent completed.*

2958. W. A. GILBER. "Improvements in treating fatty bodies and in the apparatus employed therein." (A communication.) Dated Dec. 27, 1858.

This consists, 1, in distilling neutral fat and fat acids at a regular temperature between 680° to 670° Fahrenheit in superheated steam. 2. In the employment in the distillation of neutral fats and fatty acids of an air-pump working with an intermittent motion in connection with the ordinary still and refrigerator for extracting the gases of distillation from the still as soon as formed, and by which a regular temperature between 680° and 670° Fahrenheit is maintained, the loss of the material by the ordinary process in great part avoided, and a good product obtained. *Patent completed.*

2959. J. MACPHERSON. "Improvements in solidifying the raspings and other waste of horns and hoofs, and in applying the process to the cementing of prepared horns, hoofs, and tortoiseshell." Dated Dec. 27, 1858.

This consists in subjecting the dust, shavings, raspings, &c., of animal horns and hoofs first to the action of moisture and heat, and afterwards to considerable mechanical pressure, whether to solidify the softened waste material, or to cement prepared pieces of horn to each other or to tortoiseshell. *Patent completed.*

2960. J. DAVIS. "An improved portable self gas-generating lamp." (A communication.) Dated Dec. 27, 1858.

This relates to hydro-carbon vapour-burners, and consists in the use of a heating or vaporising tube and retort charged with asbestos or any analogous material and carbonaceous fluid; ormond oil or other hydro-carbons, passing over the flame of a burner

supplied with vapour generated within the tube or retort into which the fluid ormond oil or other hydro-carbons are charged by pressure. It also consists in providing the tube and retort so charged with a cover or cup to retain the heat around its upper surface. It also consists in such an arrangement of the several parts that the fluid ormond oil or other hydro-carbons from the reservoir is supplied to the heating parts of the vaporising tube by pressure, and the entire vaporization and burning of its material effected without a residuum. *Patent completed.*

2961. C. M. A. MARION. "An improved box or case for containing and preserving sensitive photographic paper." Dated Dec. 27, 1858.

This consists of a box with a double bottom hermetically sealed, and containing in the one part chloride of calcium, and in the other the paper to be preserved. *Patent completed.*

2962. F. W. TURNER. "Improvements in steam-engines, condensers, and steam-boilers, and in promoting combustion in the furnaces of the same." Dated Dec. 27, 1858.

This consists 1, in increasing the condensing power of ordinary jet condensers, and in keeping a portion of the water which is condensed separate and distinct from the water which condenses, by inserting a cluster of brass or other metal tubes fixed vertically into a plate at their lower ends, and at their upper ends into the bottom of a shallow vessel, which vessel is supported by the tubes and is free to move vertically to the extent the tubes will expand on the application of heat. 2. In the employment and a mode of employing compressed air for condensing steam in steam-engines; also in the mode of compressing and superheating air to be used in a minutely divided shape in the fire-boxes of steam-boilers above and below the fuel, or in combustion chambers, or chambers in connection with fire-boxes or flue-tubes. 3. In a peculiar construction of combined steam cylinders to facilitate the working of high-pressure steam expansively, and to prevent the condensation or diminution of temperature of such steam while working or expanding in the cylinders by enveloping the cylinders and superheated steam in steam-tight cases; which steam in its passage to the cylinder cases passes through certain heating apparatus, and thus conveys a greater quantity of heat than is due to its pressure to the cylinders. 4. In the application of steam-tight cases on certain portions of the external surface of steam-boilers for distilling pure from impure water. 5. In certain improvements in packing for pistons. *Patent completed.*

2963. H. LOWE, W. TRUMAN, and J. L. PITTS. "A new or improved axle for carriages." Dated Dec. 27, 1858.

On an axle in which a saddle piece engaging with or sliding upon a neck near the end of the axle arm, constitutes the bearing against which the small end of the axle-box works. *Patent completed.*

2964. R. HORNBY, jun. "Improvements in ploughing and tilling land by steam power, and in apparatus employed therein." Dated Dec. 27, 1858.

In adapting agricultural steam-engines to give motion to ploughs, &c., the inventor mounts the winding drum or drums in such a position that they can be driven from the crank shaft of the engine by straight spur wheels or straight gearing without the intervention of bevelled wheels, chains, or straps, and for this purpose he in some cases mounts such drums so as to run on tubular axes, through which the axles of the bearing wheels of the engine pass eccentrically to the tubular axes. Or the drums may be mounted on studs, or axes fixed to the sides of the engine, and in either cases he arranges clutch boxes or similar contrivances, through which the power of the engine is communicated to the drums, immediately on the drums, or else on parts running at the same low speed as the drums, in place of to parts running at the high speed of the engine. *Patent completed.*

2965. B. BROWN. "Certain improvements in the manufacture of boots and shoes, or other coverings for the feet, and in the mode or method of uniting the same or parts thereof." (A communication.) Dated Dec. 28, 1858.

This relates chiefly to "Blucher" boots, and consists, 1, in making the lower and outer portion of the quarter of the upper longer than the top or middle part at the point or place of junction, so that it is made to overlap the piece in which the string is passed and secured to the front. 2. In uniting to the front or upper a strip of leather, canvas, &c., and which in some cases is made to form a side lining, and which is proposed to be continued so long and around the upper and waterproofed. The chief advantage of this strip is, that the prime part of which the front or upper is composed can be made smaller in size, as the piece serves as a portion to be taken hold of so as to

draw the upper well on to the inner sole. 3. In a mode of connecting metal tips to boots and shoes. *Patent completed.*

2966. J. SINCLAIR. "Improvements in pistons." Dated Dec. 28, 1858.

This comprehends improvements in various parts of the piston, and modifications thereof. The invention is not described apart from the drawings. *Patent completed.*

2967. T. WARREN. "Improvements in the manufacture of glass bottles." Dated Dec. 28, 1858.

Here the bottle having been blown and sauced in the ordinary way is wetted off upon a pontil, which is fitted into a case or socket and is made to revolve by a simple arrangement of gearing whilst the mouth is being formed. The mouth of the bottle is shaped by a pair of sheers carried by a stand and placed in a suitable position near the apparatus carrying the pontil, the sheers being closed upon the hot glass whilst the bottle is revolving, and thereby imparting the proper shape and finish to the mouth. The added metal for forming the thickened lip or ring of the mouth may be applied in the ordinary way, but it is preferred to have a small supplemental furnace at the side to contain the metal for lips or rings, and to take therefrom the requisite quantity by dipping in the bottle. For "wetting off" the water is made to issue upwards under a slight pressure from a semi-circular mouth, and the bottle is laid so as to expose its neck to the issuing water. *Patent abandoned.*

2968. A. LYONS. "Improvements in travelling bags." Dated Dec. 28, 1858.

This consists in uniting two bags or similar receptacles side by side through the medium of a double-framed mouth or opening, the said frame being formed of three parallel bars secured at the ends by link or spring movements which admit of the bag, when attached thereto by sewing or otherwise, being opened or closed, as also one of the bags to be turned up and placed at right angles with the other by which a cushion to the seat and back of the conveyance is formed. *Patent abandoned.*

2969. J. LECK. "Improvements in drying textile fabrics and materials." Dated Dec. 28, 1858.

Here the fabric to be dried is first placed over a steam-can or heated cylinder; it is then directed clear of the cylinder or can and passed up and over a roller of triangular section. In this way the piece is conveyed through the air and agitated in it prior to descending and passing over a second steam-can or cylinder. *Patent completed.*

2970. C. FAX. "Improvements in railway carriages and brakes." Dated Dec. 28, 1858.

This relates to a former patent, and consists, 1, in a peculiar self-acting stop motion for regulating the distance by which the brake blocks are removed clear off the wheels by the guard in unbraking the train. 2. In a self-acting and self-adjusting reversing apparatus, whereby the brakes may be used from either end of the train without the use of any extra hangers or blocks. 3. In a worm and straight rack motion applied to a carriage or waggon brakes for acting the same. *Patent abandoned.*

2971. J. H. JOHNSON. "Improvements in the manufacture of boots and shoes or other coverings for the feet." (A communication.) Dated Dec. 28, 1858.

This relates, 1, to a mode of cutting or punching out the soles, so as to produce bevelled edges at a single operation. 2. To modes and means of bevelling, reducing, skiving, shaping, buffing, and splitting the various parts of boots and shoes. The invention is not described apart from the drawings. *Patent completed.*

2972. W. HAWORTH and W. BARKER. "Improvements in the top clearers of machines for spinning." Dated Dec. 29, 1858.

This consists in making the top clearers conical, so that when they are turned round by the friction of the top rollers, there will be a rubbing action between the surfaces, which causes the flyings to accumulate evenly over the surface of the top clearers, whereas when the clearers are cylindrical the flyings sometimes collect in lumps, which falling in the yarn causes it to break. *Patent completed.*

2973. T. WELTON. "Improvements in giving or obtaining publicity, and of advertising either by day or by night." Dated Dec. 29, 1858.

Here the inventor allows artificial light either to pass through certain openings in an opaque or semi-opaque ground, such openings forming the desired letters, designs, or devices; or he uses opaque letters upon a transparent or semi-transparent ground. *Patent abandoned.*

2974. E. W. CARTER and J. D. ABRAMS. "Certain improvements in sewing machines." Dated Dec. 29, 1858.

This consists, 1, in the use of two springs, one at

each side of the shuttle for slightly confining the shuttle in its race. 2. In the use of a spring or springs within the shuttle carriage or arm to keep the shuttle in contact with the race or guide, and also in the use of two or more springs on the under surface of the covers or plates covering the race to press upon the top of the shuttle for preventing the vibrations of, and steadying the shuttle in its race. 3. In the use of a circular curved race or guide of the shuttle for causing the shuttle to move in a circular direction. *Patent abandoned.*

2975. W. TAYLOR and W. D. GRIMSHAW. "Regulating the admission of natural atmospheric air and eduction of rarefied air or gases from hothouses or any other place or premises, and for supporting a required temperature." Dated Dec. 29, 1858.

The patentee describes a self-acting ventilator or damper regulator for regulating the admission of natural atmospheric air and eduction of rarefied air or gases from hothouses, &c., and for supporting a required temperature, the said apparatus is actuated by pressure of steam, water, gas, or any other fluid, or by the temperature of the atmosphere; it is also applicable to other purposes. *Patent completed.*

2976. R. D. KAY. "An improved chemical means of applying or fixing on woven or felted fabrics certain colouring matters produced from tar." Dated Dec. 29, 1858.

This consists of means of applying on printing fabrics colouring matter produced from tar. Some of the matters used have been called harmuline, indisine, and tuchsine. The method of fixing the said colouring matters consists in the use of them in solution in combination with albumen, caseine, protein, lactarine, &c., and as these matters are not all soluble in water the inventor dissolves them in oils, or oils and alkalies, or tartaric or other vegetable acids, or a mixture of two or more of these substances. He applies the matter by blocks, rollers, &c., and subjects the fabrics so printed (after drying) to the action of steam. *Patent completed.*

2977. S. PICKFORD. "Improvements in the preparation and manufacture of manure." Dated Dec. 29, 1858.

This consists, first, in treating Sombrero Island phosphate guano, bone, caroh, or mineral phosphate with sulphuric, hydrochloric, or nitric acid, in a certain manner, by which means he obtains soluble salts, with the whole of the phosphoric acid present, or nearly so. Second, in combining the said phosphoric salts with nitrogenized substances, alkaline salts and earthy bases in such proportions as varied circumstances may require. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated June 28, 1859.

1538. G. Dawes and C. J. Carr. Certain improvements in atmospheric and vacuum hammers and stamps, part of which improvements is also applicable to steam and other engines.

Dated June 30, 1859.

1560. J. LAWSON. Certain improvements in machinery for roving, twisting, and spinning flax, cotton, wool, and other fibrous substances.

Dated July 6, 1859.

1602. J. LUIS. An improved mode of manufacture of wheel tires for railway carriages and engines, by means of the therein described apparatus. A communication.

Dated July 8, 1859.

1623. J. GIBBS. Improvements in the manufacture of brushes, brooms, coverings for floors, mats, scrapers, and other scraping and rubbing surfaces.

Dated July 12, 1859.

1632. J. LUIS. Improvements in railway car seats and arm chairs. A communication.

1653. C. J. PROAL. The application of photographic impressions or pictures upon fabrics or tissues, for rendering such fabrics or tissues applicable to various useful purposes. A communication.

Dated July 19, 1859.

1698. J. LUIS. A new system of eccentric socket adapted to axletrees. A communication.

1702. J. C. RIDDEL. Improvements in stalls, loose-boxes, and enclosures for horses, cows, pigs, or other animals.

Dated July 20, 1859.

1704. T. CURTIS and J. HAIGH. Improvements in the finishing of cloths.

Dated July 21, 1859.

1711. J. TODD, jun. Improvements in machinery or apparatus for dressing or cleansing and separating grains and seeds.

1712. G. WELCH. An improvement or improve-

ments in the manufacture of frames for mirrors, pictures, and other articles.

1713. I. Robson. Improvements in means or apparatus for drying and cutting cotton warps after being dyed or sized, or after any other process of wetting, and when quick drying is required.

1715. M. Henry. Improvements in apparatus or machinery for the manufacture of corks and bungs. A communication.

1716. E. J. and S. F. Scott. Improvements in the manufacture of boots and shoes.

1717. H. Healey. Improvements in machinery for destroying flies and other insects on growing crops.

Dated July 22, 1859.

1718. J. Hartley. Improvements in machinery for regulating the velocity of steam and other engines.

1719. J. G. Iaham and S. D. Albertson. Improved machine for cutting and shaping bottle and other corks. A communication.

1720. S. A. Bell and J. Black. An improved manufacture of fuses.

1721. W. E. Newton. Improvements in sewing machines. A communication.

Dated July 23, 1859.

1722. J. B. Whitehall and S. Wheatcroft. Improvements in the construction of certain parts of the apparatus or machinery made use of for manufacturing bonnet and cap fronts, rouches, and such like articles of millinery.

1723. H. N. Harrop, jun. Certain improvements in a cigar lighter and fuse box.

1724. J. Broadley. Improvements in means or apparatus used in weaving.

1725. J. Tenwick. Improved steering apparatus for ships.

1726. W. H. Harfield. Improvements in capstans, riding bits, and stoppers for working with chains.

Dated July 25, 1859.

1727. H. Ambler. Improvements in explosive projectiles.

1728. J. Rowland, jun. Improvements in machinery or apparatus for sizing yarns or threads, which said improvements are also applicable to dressing machines, or other similar apparatus.

1729. G. Davies. Improvements in dyeing yarns, threads, or woven fabrics, of wool, silk, cotton, linen, or other fibrous or filamentous material. A communication.

1730. E. Hunt. Improvements in apparatus for indicating and regulating speed.

1731. W. E. Newton. Improvements in extracting oil from coal, and other substances yielding pyrogenous oils. A communication.

1732. C. F. Vasserot. Preventing and removing incrustations in steam boilers. A communication.

Dated July 26, 1859.

1733. J. King. Improvements in the treatment of materials used in, or resulting from, the distillation of spirits.

1735. J. H. Johnson. Improvements in slide valves for steam-engines. A communication.

Dated July 27, 1859.

1741. E. Winstanley. Improvements in indicators for registering the quantity produced by spinning machinery.

1743. T. Dickens. Improvements in dyeing and discharging warps or other yarns or threads, and woven fabrics of silk, wool, cotton, and other fibrous materials.

1745. C. L. Blum. A mechanical apparatus for smoking and colouring pipes.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

(From the London Gazette, Aug. 9, 1859.)

756. R. Baker. Timekeepers.
767. J. C. Evans and P. Soames. Superheating.
771. J. Buckley, O. Greenhalgh, and R. Hutchinson. Printing fabrics.

773. C. F. Vasserot. Diving apparatus. A communication.

781. J. W. Kelly. Gas burners.

801. W. and E. Smith. Regulating.

802. J. Lucy, S. Simpson, and H. Smith. Spinning.

804. R. C. Ross. Cultivating land.

808. D. B. White. Gauge-lead or plummet.

834. T. Williams and J. H. Fuller. Screw stocks and dies.

836. J. Eccles. Bricks, tiles, &c.

840. J. H. Burton. Barrels for fire-arms.

843. C. Russell. Marine engines.

846. E. Morewood. Coating metals.

847. D. Sowden. Jacquard machines.

857. N. Libotte. Cages for drawing coals.

862. W. Owen. Wheels and tyres. Partly a communication.

863. J. Rogers and E. J. Tweed. Coating conducting wires.

871. J. Garrett. Goblets, jugs, &c.

872. J. Rawlings. Boot tree.

873. J. T. Pitman. Fireworks. A communication.

878. M. A. F. Mennons. Articulated joint. A communication.

879. M. A. F. Mennons. Phosphates of lime. A communication.

890. J. Hawkins. Stirrups, bits, &c.

912. P. Aitchison. Taps.

918. M. Castay. Metallic bridges.

933. J. Hughes, W. Williams, and G. Leyshon. Tin andterne plates.

982. W. Parsons. Preparing metal sheets.

1010. T. S. Truss. Pipes.

1028. W. Stevenson. Spinning, doubling, &c.

1038. W. E. Newton. Sewing machines. A communication.

1084. J. Darlington. Zinc retort furnaces.

1120. J. G. Willans. Utilising peat.

1162. A. V. Newton. Lamp. A communication.

1180. T. P. Bennett. Carding engines.

1207. C. E. Amos. Raising vessels.

1303. J. C. Bent. Gas-meters.

1313. P. Aitchison. Water closets.

1638. G. Dawes and C. J. Carr. Hammers and stamps.

1648. J. Dible and W. H. Graveley. Ventilating and lighting ships.

1688. J. Morgan. Candles.

1724. J. Broadley. Weaving.

1727. H. Ambler. Explosive projectiles.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed August 5, 1859.

154. J. Fawcett.	376. W. A. Covert.
218. J. G. Proger and D. Davies.	377. R. J. Ellis.
338. G. F. Chantrell.	429. R. J. S. Pearce.
346. J. Smith.	456. W. Clark.
350. J. Hosking.	493. G. Paul.
356. J. B. Redman.	505. J. H. G. D. Wagner.
361. E. Wilkins.	512. C. W. Siemens.
362. J. S. Joseph.	525. A. Martin and A. Chrichton.
368. G. Bower.	618. W. E. Newton.
369. J. E. McConnell.	680. A. Mein.
371. E. Herring.	744. J. H. Johnson.

Sealed August 9, 1859.

386. H. Bruce.	405. R. Bell.
390. T. White and G. Jenkins.	411. J. Wright.
400. J. and J. Bennett.	500. R. Mushet.
401. G., G. W., and J. Betjemann.	501. R. Mushet.

PATENTS ON WHICH THE THIRD YEAR'S STAMP DUTY HAS BEEN PAID.

1840. H. W. Wood.	1885. J. Cartland.
1848. J. Keith.	1913. W. Tranter.
1854. J. Y. Borland.	1939. J. Brouard and J. Hubert.
1876. T. Whittaker.	

LIST OF SPECIFICATIONS, &c.,

Published during the week ending Aug. 6, 1859.

NOTE.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office.

LIST OF MISCELLANEOUS TENDERS INVITED, AND ENGAGEMENTS OPEN.

The tenders and vacancies which appear in this weekly list are not repeated in succeeding numbers.

ENGINE, BOILER, AND FORCE PUMP, *Ireland*.—For throwing up a supply of water to the Constabulary Barracks, in the Phoenix Park, Dublin, from a point 88 ft. in level and 2,350 feet in distance below. The engine to be 6-horse high pressure. Tracings and information of the Secretary, Office of Public Works, Dublin. Sketches of engine and proposed arrangements to accompany the tenders up to August 27. E. Hornsby, Secretary.

IRON SUPERSTRUCTURE TOWER BRIDGE, *East India Railway*.—Specifications, drawings, and bills of quantities, at the Office, East India Railway House, Aldermen's Walk, London. Tenders August 16.

WROUGHT IRON PLATFORM, *Berke*.—At Able Bridge. Plans, &c., with bills of quantities and forms, Mr. J. B. Carey, County Surveyor, 90 Broad-street, Reading. Tenders, August 24.

IRON PIPING, *Bolton*.—1,150 lineal yards of iron pipes of 12 inches diameter, and a further quantity of 2,400 yards of 6 inches diameter. Particulars, Borough Surveyor, Corporation Offices, Acres-field.

IRON ENTRANCE GATES, *Hanley*.—And fencing to the Borough Cemetery. Particulars, Surveyor's Office. Tenders, August 17, to the Town Clerk.

CHAPEL, *Morley, near Leeds*.—For the erection. Plans, &c., by applying to the Chapel Keeper.

CEMETERY CHAPEL, ENTRANCE LODGE, BOUNDARY WALL, &c., *Farnley*.—Drawings, office of Mr. Hill, Architect, 71 Albion-street, Leeds. Tenders to Chairman of Board to August 23rd.

PARSONAGE, *Pilcombe, Somersetshire*.—Plans, Rev. Vernon Taylor, Wyke, near Bruton. Tenders to August 30th.

SCHOOLS, *Little Hodham, near Bishop's Cleeve, Herts*.—Plans, &c., Mr. G. E. Pritchett, 12 Bishopsgate-street Without, and Bishop's Cleeve. Tenders to August 19th.

SCHOOLS, *Epping, Essex*.—For the erection of 3 large schools and double residences. Plans at office of the Architect, Mr. G. E. Pritchett, 12 Bishopsgate-street Without, and Bishop's Cleeve. Tenders to August 19th.

SEWERAGE WORKS, *Manchester, Township of Cheetham*.—For sewerage, paving, &c. Plans, Mr. William Frances, Surveyor, Town Hall. Tenders to August 26th.

REMOVING ASHES, &c., *Bradford*.—Emptying and carting away the contents of all ash-pits and cesspools within the district of the Local Board of Health for one or three years, from the 1st of September next. Tenders to the Chairman, the Office, Mill-lane, Bradford, (where any further information) August 22.

NEW MARKET OR SHAMBLE, *Pontefract*.—Plans and specifications at the Town Hall. Tenders to H. J. Coleman, Esq., Town Clerk, before the 28th instant.

FOR TAP.—Tenders for the tap which shall be produced at the Surrey Gas Works, Rotherhithe, S. E., during the 12 months commencing 1st Oct. next, will be received there until the 18th instant.

ATLANTIC CABLE.—The Atlantic Telegraph Company invite inventors, patentees, and manufacturers of submarine cables calculated for laying across the Atlantic, to send the same to the Secretary of the Company, (Mr. George Seward, 22 Old Broad-street) together with any description they may desire to append to them, in order to their being submitted to the officers of the Company, and by them to the Consulting Committee for the purpose of examination, testing, and experiment.

PLANS FOR MARKET-HALL ROOF, *Wolverhampton*.—Designs to be forwarded to the Borough Surveyor to 27th of August. Plan and particulars at the office of the Borough Surveyor.

TOWN SURVEYOR, *Bilston*.—To take charge of the roads, make plans, superintend all contracts connected with the sewerage, water supply, and all other works, from time to time carried on by the Commissioners of the Township. Salary £100. Applications to Mr. Viles, Clerk, August 15.

SURVEYOR.—Accustomed to town work, the use of the theodolite, able to plot his own work, and make a finished plan. Applications stating real name and address, age, previous employment, and salary required, Box 64, Post-office, Manchester.

SURVEYOR AND INSPECTOR OF NUISANCES, *Moss Side, Manchester*.—To undertake the entire duties, and to devote the whole of his time as Surveyor and Inspector of Nuisances. Salary not exceeding £100 per annum. Application in writing to the Clerk, (Mr. J. H. Hampson) August 31.

INSPECTORS OF GAS FITTINGS, *Manchester Corporation*.—Two. Must be practically acquainted with the business. Salary £90 each. Applications, with testimonials, to the Chairman of the Gas Company, York Chambers, King-street, August 21.

GAS MANAGER.—A steady active man to undertake the management of a small gas work, and make the gas. One who understands fitting will be preferred. Applications, with references, Mr. Munday, Madeley, Salop.

WORKING GAS MANAGER.—For the Uttoxeter Company, to attend to the making of the gas, laying the services, fittings, &c. Wages, 30s. a week, with house, coal, gas, and allowance of £1 a year, in lieu of garden. The manager to pay his own stoker out of the above wages. Applications in writing to Mr. Fradgley, Architect and Surveyor, Uttoxeter.

FORMAN MOULDER.—Accustomed to first-class engine and tool work. Box 32, Post-office, Manchester.

BLEACHWORKS MANAGER.—One who can take the whole management will be respectfully treated with. References required. X, 90, *Guardian* office, Manchester.

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, AUGUST 19, 1859.

OUR NATIONAL DEFENCES.

It is a comforting thing to know that while so many are deploring our want of national defences, so many are also telling us of innumerable methods by which we may readily secure ourselves from attack. One informs us that we may do this by building twice as many line-of-battle ships as we now have; another advises us that half-a-dozen steam rams will make us safe; another, that five hundred gunboats will answer the purpose; another, that fifty thousand additional seamen are all that we need; another, that a marine militia manning gun-rafts is the thing; another, that martello towers and land batteries alone need multiplication; another, that railway batteries from point to point of the coast would make us invulnerable; another, that a large increase in our militia force would be an ample safeguard; another, that a triplication of our standing army is alone desirable; and so on.

It would be mere pedantry in us to pretend that the question of our defences is a simple one. It is far from it; and he is a wise man who keeps his mind ready for the free reception of any new light that may break upon the subject. Such a man will have his eyes open to all that transpires in reference to our naval and military forces, and especially to the *matériel* of our army and navy. We have ourselves looked through very many of the numerous disquisitions which writers who know something and others who know nothing of the subject have written, and it may be of service to many of our readers if we say that the best of them is, in our judgment, that which appears in the July number of the *Quarterly Review*. This article is from the pen of a gentleman who has good grounds for speaking confidently on some of the important topics embraced by his remarks, and who has taken pains to acquire reliable information on others of which he may properly be supposed to have known less.

We observe with pleasure that the author of this able paper, while exceeding on some points the statements which we have made, on others most strongly enforces what we have frequently urged during the last six months. On the subject of iron-coated ships of war, for example, he writes much to the purpose. After alluding to the experiments which have been made in connection with this subject, and remarking that, as we have often said, we cannot hope to make our ships proof to solid wrought-iron shot, but have the means of making them shell-proof, he says when this conviction was forced upon the Admiralty they began to stir themselves; "and, after having obtained designs and tenders from the six most eminent iron-shipbuilding firms in England, they have given orders to a newly-formed 'Limited Liability Company,' who, whatever their other qualifications, can by no possibility have the necessary experience." If, however, he continues, they do execute their contract, this one vessel may be ready for sea in June next. It is said the Admiralty will then consider whether or not they ought to proceed further. In the meantime—says our Reviewer—it would be difficult to find a single naval officer of ordinary intelligence who is not aware that the day of wooden vessels of war is past, and that when two ships approach within fighting distance, one at least will be disabled, probably sunk or burnt, in a very few minutes. "In fact, nothing can keep the seas but incombustible shell-proof vessels."

The one question which remains open seems to be whether or not wooden ships coated with iron slabs of only one or two inches in thickness would not meet most of the difficulties of the case. If so, we could in a short time convert some of our wooden walls into efficient vessels of this class; but it is nearly certain that if any other nation should possess shell-proof fleets, while we do not, they may be able to wrest the dominion of the seas from us by the employment of this expedient alone. The cost of providing such ships must, of course, be very considerable. The danger, however, is so imminent that the outlay is indispensable to our safety, and not one hour should be lost in attempting to overtake our rivals. The money spent in providing a squadron of six or seven of these ships would probably do more to ensure our supremacy on the ocean than any other outlay which can at present be suggested. It is true that the French vessels may not—indeed, cannot—turn out to be first-rate sea-boats, nor capable of being used on long voyages; but they certainly will be equal to a cruise across the Channel, and for covering a disembarkation of troops, and employed against shore batteries would prove of the utmost importance. The French therefore possess an arm which we do not, and which we cannot have by any exertion within twelve months. If it proves as important in practice as the best informed assume it to be in theory, its absence may suffice to turn the tide of battle against us. All this we have often said before, and we only say it again because of the new interest which the *Quarterly* has given the subject by reviving our statements, and because the subject itself is of vital importance to the nation.

In discussing the probable effect of steam propulsion in favour of the attack or defence of our shores, the Reviewer adduces considerations which well deserve attention. He notices particularly the difficulty of blockading an enemy's port by a steam fleet. As it is manifestly impossible that a fleet can carry a sufficient quantity of coal to blockade under steam alone, the squadron keeping the sea must be fully rigged; while the enemy issuing from their cover under steam, and if they please without masts and spars, would have an immense advantage. This last condition, of the issuing enemy being without masts and spars, is a most important one. All will, as the Reviewer says, recollect the dreadful fate of the steam-ship *Prince* in the storm off Balaklava. She was a screw vessel steaming successfully to windward, and in a few minutes would have been safe, when the order was given to cut away the mizen for the purpose of easing her. It fell overboard and fouled the screw, when she at once became an unmanageable wreck, and perished with all on board. And why may it not be so in future naval actions? One shell in a mast will suffice to send it by the board, and the screw will certainly draw in some part of the wreck. If once the ropes become entangled with the screw, it must either be disconnected, raised upon deck and freed, or the vessel will become helpless, and altogether incapable of moving or steering. So apparent is this danger, that many officers are inclined to recommend a recurrence to the old paddle-wheel instead of the screw—at least for small vessels, not requiring many guns. Sir Howard Douglas, as our readers know, proposes to greatly diminish the chances of evil in this respect by altering the form of the leading edges of the screw blades, shaping them so that they may act like knife-edges, and clear themselves of ropes or other encumbrances. The results of late experiments on the *Doris* pointed so strongly to other advantages associated with the changes proposed by Sir Howard, that we

are at a loss to know how it is that further experiments have not already been instituted. Sir Howard has made application, we believe, for permission to have his plan carefully tested under his own superintendence on board a ship of war; and when the eminent services already rendered by him to the navy are considered, and to these are added the promise of success which the experiments just referred to afford, there can be, we think, no reasonable, or even justifiable, grounds for a refusal to his request. The *Quarterly Reviewer* considers the defect in question—the fouling of the screw—would be cured by adopting an arrangement which, he says, "has been used in the mercantile marine with perfect success for the last five or six years." This consists in placing the screw quite free of, and entirely behind the sternpost, instead of in an aperture in the deadwood of the vessel, and then, by making a joint or hinge in the screw shaft, it can be easily raised outside the vessel without being disconnected. In this position it is almost as little liable to be fouled as a paddle-wheel; but if the accident should happen, it can be cleared and lowered again in a few minutes. "It is merely necessary," says the Reviewer, "that there should be two sternposts instead of one, placed side by side, with a slit between them, up and down which the shaft can be moved with facility. The rudder is placed wholly below the screw-shaft, and entirely out of danger. Such an arrangement of the screw seems to get over all the known difficulties without any counteracting disadvantages, and why it is not adopted is one of those mysteries only known to Admiralty Boards." If the Reviewer is right, and this plan—which was originated, we believe, by Mr. Scott Russell, and is in use in some of his vessels—can be adapted to ships of war of all classes, its adoption would undoubtedly add enormously to their safety.

Gunboats are a class of vessels upon which careful attention is bestowed in the article before us. For defensive purposes they are of the utmost importance, and are by no means an expensive expedient. In the good old times it used to be estimated that every gun on board a man-of-war cost £1,000. Owing to the changes which steam has introduced this is now nearer £2,500 in a line-of-battle ship, £3,000 in a first-class frigate, and £3,500 in a corvette. The iron-coated ship building at Blackwall will cost not less than about £8,000 per gun! Whereas a single-gun gun-boat can be built for £2,500, and, if protected with iron, for at least as small a sum per gun as the large vessel of the same kind. As the "light infantry of a fleet" to protect harbours and prevent a landing, they would be invaluable, and, what is very important, they can easily be built in private yards in any number and in very much less time than would be required for a proportionate increase of the regular navy. A thousand of them would certainly, as a subsidiary force, go further to render our shores free from insult than ten line-of-battle ships. They would also be far more easily manned, being a class of vessel which our fishermen and coasting sailors would gladly volunteer to serve in. A fleet of gunboats would also be far less liable to disaster, for the destruction of one or two would hardly be felt in a squadron. If overpowered, they could escape into creeks and shallows, where they could not be followed; and there is no class of warfare, as the Reviewer says, which would tend so much to bring out the best points of an Englishman's character and seamanship as a guerilla warfare of this sort. A fleet of gunboats of our own would also enable us to defend Woolwich and London from an attack of foreign gunboats ascending the Thames. This we have no pre-

sent means of doing. Tilbury and other land forts would be useless for such a purpose; for vessels under steam cannot be hit with any degree of certainty from the shore. We have it on the authority of Captain Coles, the designer of the *Lady Nancy* raft, that our gunboats were frequently attacked by Russian artillery from the shore during their expedition in the Sea of Azoff, but always with little or no effect. And no doubt French or other gunboats might traverse our rivers at high speed with the same impunity. A fleet of gunboats of our own would not only remedy this defect in our defences, but would also give us the power of carrying successful war into the hearts of hostile cities.

THE NEW WORKS DEPARTMENT OF THE ADMIRALTY.

THERE are many men who possess, or affect, an imperial tone who have nothing imperial in their faculties. While too haughty to take counsel of others, they have not the ability to do wisely of themselves. There are many small administrators of this kind in office, and we pay very dearly for them. Indeed such men are in every department of the Government putting terrible burdens upon our shoulders, even if they are not, as some suppose, jeopardising the very power and honour of the nation. There is not a man of any observation among our readers who has not been more or less pained and chagrined by the acts or the no-acts, the folly or the supineness, of such officials.

Now, we do not wish to bear hardly upon any man or men, but the time has come for us to say that the New Works Department of the Admiralty seems to be managed with too much hauteur and too little knowledge. From many quarters, and for a long period, we have received complaints of the manner in which the buildings, roads, and other like constructions have been carried out in our dockyards, under the management of Colonel Green and his assistant, Mr. Scamp. It would really appear—monstrous as the statement may seem—that it is the habit of these gentlemen to conduct their works with little or no reference to the desires, or even to the necessities, of the officers for whose uses they are intended. For example, a man of plain sense would suppose that if a building, or set of buildings, is to be erected for the use of the factory in a dockyard, the chief engineer of that factory would be consulted upon all the main and most of the minor features of the work, since it is he who has experienced the necessity of what is wanted, and it is he also who will have to put it in operation when it is constructed. But not so: the two gentlemen at Somerset House, being men of uncommon sense, consider themselves the proper, and too often the only, persons whose knowledge is to be made available, and whose wills are to be consulted. The fruit of all this is, that of late years our great and costly dockyards have been cut about and blocked up in a most remarkable manner. In Sheerness Dockyard, for example, of which we know perhaps more than any other, some truly abominable changes have been made, especially in the architecture of the place. A few years since the centre of the yard was occupied by a large and noble four-sided brick building, used as a storehouse. This building stood quite alone, and at a sufficient distance from all others to produce its full architectural effect, which was very imposing. At a short distance from it stood the blacksmiths' forge—a building, of course, of a totally different style and character, but not sufficiently near to break the unity of effect which the larger structure produced. Of late years, however, the gross folly—one might

almost say sin—of connecting these two buildings by blank brick walls has been perpetrated; and thus on three sides the beauty of a large and costly edifice has been not only marred, but destroyed altogether. Again; until recently the entire harbour-face of the same dockyard consisted of a continuous line of granite wall, straight and uniform from end to end, and relieved by breaks at the basin entrances. Lately, however, a black wooden structure has been built out into the harbour near the middle, and now stands there an annoying and enduring defacement of what was before pleasant to behold.

But let it not be supposed for a moment that egregiously bad taste is the only, or the worst, thing we have to charge the Department of the Director of Works with. A man may have no soul for art, even in its most manifest forms, and yet know how to dispose of space judiciously, to build a workshop efficiently, or to lay a roadway securely. These things, however, or at least some of them, seem to be beyond the ability of the Director of Works and his people. If any man with two eyes in his head,—or indeed a man with one eye, or even “half-an-eye”—will take the trouble to walk through Sheerness Dockyard just now, he will see plainly enough that the laying down of a road for a wheeled truck to run upon is an undertaking that Colonel Green and Mr. Scamp, or their subordinates, are not yet in a position to accomplish satisfactorily. In that yard a very excellent and economical system of transporting and storing boilers has been devised and introduced by Mr. Blaxland, the Chief Engineer of the establishment. The boilers of many of the steam ships now continually lying in the dockyard or harbour at that port have in many instances to be transported to and from the factory for repair, and when their repairs are completed have to be stood aside, often in considerable numbers, until they are again required for use on board ship. The transport of these boilers by means of the ordinary appliances of the dockyard was found to cost so much for labour, and to be attended by so much delay, that Mr. Blaxland set about proposing a remedy. He has accordingly devised a pair of trucks or carriages, of which the lighter runs off and on the heavier, upon rails. When a boiler is to be removed the upper carriage is run in beneath it upon rails, and the weight of the boiler is received upon it. This upper carriage, with the boiler upon it, then retraverses the rails, and is received upon the main carriage which bears it away to the storing ground. There are many and great advantages attending this system, one of the chief being the extreme facility with which the boilers when stored could be got at and hurried away to the ship in case of an emergency, every thing which facilitates operations of this kind being of great value in these times. Another similar and equally important advantage attending the plan is, that pairs or sets of boilers can be readily placed in their proper relative positions on the storing ground, and there have all their pipes and other appliances fitted to them, so as to be fully ready in all respects to be put together for service at the shortest notice.

Now this arrangement, which reflects great credit upon its author, and is calculated to save the country much expense, requires, manifestly, that a road suitable for the main carriage to run upon from place to place should be laid down. The construction of such a road was accordingly undertaken by the Director of Works; and how does the reader suppose this gentleman and his colleagues have formed it? With an amount of wisdom which it requires a great stretch of faculty to duly appreciate, they have constructed it of small detached blocks of wood

stood up on end upon a shallow layer of concrete! The consequence is, as the carriage wheels roll along, little block after little block sinks beneath them, and every succeeding block of course becomes an obstacle to the carriage's progress. Three times the power which would be sufficient to move it over a hard and firm road is consequently required, and the road-way itself, although new in many parts, is already so rugged as to be little or no better, or more suitable for the purpose, than the stone road-way before us here in Fleet-street! No one, if he should think our statement of facts too bad to believe, need receive it simply upon our allegation. He can go to the dockyard, and walk over the ground himself, and gradually—for it takes time to do it—gradually, we say, persuade himself that what he sees is real and true.

So bad is the management of this department of new works now under notice, that even Mr. Murray, although he had so much that was strange of his own to discourse upon, could not help going out of his way to attack it in his late manifesto. He says:—“With respect to new works, the Committee found a general expression of dissatisfaction on the part of the practical officers, both as to the opportunities afforded to them for expressing their opinions on works intended for their use, and the little attention paid to their representations when made; and the Committee feel obliged to express their opinion that much loss has resulted to the service from this cause. At the same time, opportunities appear to have been given to the practical officers occasionally to state their views; but from this having been done generally in a cursory manner in conversation, and the opinions having been given hastily, and sometimes, perhaps, not understood, or not appreciated, the result has been very unsatisfactory. Perfection in arrangements, and consequent economy in manufacturing, depends much upon the details of the buildings in which the work is to be carried on; but the Committee have found that many buildings have been far advanced before the details were determined upon, and inconvenience in the position of the necessary adjunct buildings and other evils have resulted. The practice prevails of the clerk of the works being directed to consult with the other officers and make out plans, and these plans have then been forwarded and final plans have been sent down from London, and the contract taken and the work begun, without any of the officers, for whose use the works were intended, having seen them.”

This is not a very luminous statement, but it reaches, however indirectly, the point we are aiming at; and for the sake of backing up facts which we have seen with our own eyes, we do not mind raising even Mr. Murray's report to momentary importance. There need be no fear of its speedily sinking again to its due obscurity.

THE BUILDERS' STRIKE.

BOTH men and masters have an undoubted right to combine for the management of their own affairs; but union is strength, and when men are very strong they are exceedingly likely to abuse their influence. Workmen, who have been very fond of combining of late years, have undoubtedly gone very wrong in this respect. Without discussing doubtful details, we may mention one great instance of their tyranny: they constantly refuse to work with men who have not joined their trade societies. In many instances they have struck work simply because a non-society workman has had employment given him by the master.

Although this has not yet been made a legal offence, it is a moral one; for it practically deprives the master of his fair degree of liberty, and imposes a heavy penalty upon every man who conscientiously objects to share the proceedings of the societies.

To resist such mischievous and tyrannical proceedings as these the masters would do well to combine, and it would be a blessing to thousands of workmen, as well as to society at large, if they became triumphant in their resistance, and put an end to the despotism of trades unions. For success on this one point would destroy the "despotism" of such bodies. If working men were free either to join or to stand aloof from such societies, without suffering personal loss, all the oppressive powers of the societies would at once cease. It is only because they have contrived to impose a penalty upon the working man who dissents from them that they have become so strong and overbearing. If, therefore, the Metropolitan master builders had been well-advised, they would not have insisted upon the men promising not to combine at all on the labour question, because the men have an undoubted right so to combine if they please. What they should have insisted upon is, that the men whom they employed should pledge themselves to abstain from that particular act of tyranny which we have pointed out, and from such other specific acts of a tyrannous character as they, the masters, may be able to mention. This would have commanded the unanimous approval of the press, and would have left the society men without any plausible pretext for resistance. At any rate it would have brought the real and not an imaginary case forward for decision, and would have given the men no chance of selecting false ground for their battle-field. As it is, we have the men on the one side contending for an arbitrary limitation of working hours, and the masters on the other enforcing an equally arbitrary arrangement of their own.

That the men's demand for the enforced reduction of the working hours from ten to nine is an arbitrary and unfair demand is shown by the fact that it is only by the tyrannous acts of the societies that it can be maintained. If non-society men were permitted to exercise free trade in their labour, we should hear nothing of the nine hours' movement. And that they ought to be permitted to do this there can be no doubt. Lord Brougham, in his "Rights of Industry," has stated the terms of the workman's freedom most clearly, and these terms are all that a reasonable man can require. "There can be no doubt," he says, "that the labourer has rights over his labour which no government and no individual should presume to interfere with. There can be no doubt that, as an exchanger of labour for capital, the labourer ought to be assured that the exchange shall in all respects be as free as the exchanges of any other description of property. His rights as an exchanger are, that he shall not be compelled to part with his property, by any arbitrary enactments, without having as ample an equivalent as the general laws of exchange will afford him; that he shall be free to use every just means, either by himself or by union with others, to obtain such an equivalent; that he shall be at full liberty to offer that property in the best market that he can find, without being limited to any particular market; that he may give to that property every modification which it is capable of receiving from his own natural or acquired skill, without being narrowed to any one form of producing it. In other words, natural justice demands that the working man shall work when he please and be idle when

"he please—always providing that if he make a contract to work he shall not violate that engagement by remaining idle; that no labour shall be forced from him, and no rate of payment for that labour be proscribed by statutes or ordinances; that he shall be free to obtain as high wages as he can possibly get, and unite with others to obtain them, *always providing, that in his union he does not violate that freedom of industry in others which is the foundation of his own attempts to improve his condition*; that he may go from place to place to exchange his labour without being interfered with by corporate rights or monopolies of any sort, whether of masters or workmen; and that he may turn from one employment to the other, if he so think fit, without being confined to the trade he originally learnt, or may strike into any line of employment without having regularly learnt it at all."

These are the conditions on which working men exercise their labour and skill in this country. If the conditions are wrong, or can be improved, let us have the subject amicably discussed, and a public understanding arrived at. It is mere folly for the builders or any other class of men to attempt to set them permanently aside by the coarse coercion of strikes; and it is also mere folly for masters to meet the coercive measures of the men by any mode of action which is opposed to these conditions.

THE NEW BRONZE COINAGE.

FROM the evidence of Doctor Graham, Master of the Mint, as given before the late Decimal Coinage Commission—that is, before Lord Overstone—we gather that gentleman's opinion as to the value of bronze as a material for coins, which opinion, on the eve of a new coinage of mixed metal, becomes especially valuable. In July, 1857, the present Master of the Mint stated that the French Government had materially diminished the size of the inferior coins of the French empire, and that the change had been a very popular measure. He also believed that a similar alteration might be beneficially made on this side of the Channel. As in France bronze had been used in place of copper for the new currency, so would he have it used here. When questioned as to the proportions of the various metals necessary to form a mixture at once hard and attractive in appearance, Dr. Graham replied that the bronze of the ancients could scarcely be improved upon, and that the French bronze was analogous to it. Bronze, said this eminent authority, has numerous advantages over copper, of which the preservation of the coin in a better condition is one; among its other advantages may be mentioned that in consequence of its being much harder than copper, the pieces of money struck from it may be considerably thinner, so that lightness might be obtained without an inconvenient sacrifice of size. One remarkable advantage, too, it possessed, which was that counterfeit coins could not be made to resemble in colour coins of mixed metal. It was possible, and, indeed, easy to coat metals by the electrolyte with pure copper, but it was impossible to coat them with a composition like that of bronze. Further testimony of a similar kind or tending in the same direction was given on this occasion by the Master of the Mint, and it must be very satisfactory to the public to know that in the new bronze they are likely to get, in all respects, a better article, and one which will be much cheaper, than the pure copper coinage of which the Mint, we may suppose, has now struck its last piece.

The chief misgiving we now have upon the subject of the new issue of bronze monies is,

that it will be too long about. Of the task of producing the large number of tons necessary for effecting a simultaneous exchange of old coins for new ones, it may be said in the language of Shakspeare:—"If 'twere done, when 'twere done, then 'twere well 'twere done quickly." We have before had occasion to speak of what was accomplished in 1816-17 with regard to the exchange of the worn and torn silver coins of previous dates, and it would be idle to suppose that the Mint could not effect very much more now than it did then. Nevertheless, increased facilities, mechanical and otherwise, would doubtless be required. The vote of £10,000 does not seem large enough to commence so gigantic a work as the creation of 6,000 tons of new coins; but judiciously laid out it is certain that much may be done with it. Converted into pence, halfpence, and farthings, of something like the dimensions adumbrated in our last article, and bought up by the public, the £10,000 would soon be quadrupled, and Government would thus have increased capital in hand wherewith to go again into the metal market. Perhaps, indeed, this is the thrifty and economical design of the Chancellor of the Exchequer. The hon. gentleman, aware of the "ignorant impatience of taxation" existing among Her Majesty's lieges, thought that he had better tone down his demands, and whilst exhibiting his own knowledge of commercial economy quiet the grumblers inside and outside the House. At any rate, this is a much more rational theory for reducing the estimate to one-fifth of the sum originally considered necessary, than the notable one of buying the plant for a contractor's mint at Birmingham or elsewhere.

We shall be glad to hear that the authorities of the Mint are looking the important duty fully in the face, and taking effectual means to accomplish it. Speedily, we learn, the steam power of the establishment will be equal to 100 horses, and surely no paucity of mechanical appliances should prevent the production of as great a quantity of coins as this power properly employed would effect. Nothing less than two millions per week ought to be the rate at which Her Majesty's benign features should be impressed upon the new bronze discs at the Mint, and this is a speed which, without contractor's aid, might, we think, be easily attained there.

As to the designs for the coming coinage, we have already suggested the advisability of open competition among engravers—with the offer of a prize or prizes—and we now propose, in addition, the nomination of a *mixed* jury to decide as to the merits of the various works. We say a *mixed* jury advisedly, for a purely artistic one would not do. You must have something more than a beautiful and appropriate creation of the mind and the pencil; you must have that which will not only show well on paper, but which may be easily and rapidly transferred after engraving from the die to the disc of metal to be impressed. In short, the accepted design must be one which will look well, coin well, and wear well. Hence the necessity for a *mixed* jury—half practical, half artistic.

The Mint engraver might, of course, compete with out-door artists, and the award would, no doubt, be given to the most meritorious and practicable design. It will be, in this instance, too late to retreat when once the "die is cast," and hence our urgent desire to make sure of winning. To stamp into existence in England, in 1859, a new coinage which would not in all respects—artistical, mechanical, proportionate, and durable—bear a favourable comparison with any coinage in use abroad, would be to stamp ourselves with indelible disgrace. National works have, however, so often proved

national failures, that there is some reason for anxiety even in the introduction of a new coin. Whilst, therefore, all proper haste in effecting the reform is counselled, and red tapery is denounced *in toto*, it may be hoped that sufficient care will be taken to guard against an error which would be irretrievable. Doctor Graham is, no doubt, sensitively alive to the responsibility of his office, and in his hands the public interests so far are in safe keeping.

FREE DRINKING FOUNTAINS.

NOT until this year of grace 1859 have we English people had the good sense to give the poor men, women, and children of our streets a free cup of cold water in the name of Christian charity. In this metropolis and other large towns we have, by our neglect, driven our poor street population incontinently into the beer-house and dram-shop. We have been very loud and very active in our zeal for the working classes. We have exclaimed against their drunkenness and sighed over their depravity; established huge societies for their reform and built churches for their salvation. And we have doubtless in these ways done much for their good. But the simple expedient of putting up a water fountain in competition with the gin-shop—of offering a free cup of pure water instead of an expensive glass of fiery poison, has not until now occurred to us. All honour to Mr. Melly, who, a year or two since, began the humane work! All honour to Mr. Smithies, to Mr. Wakefield, the Earl of Carlisle, the Earl of Shaftesbury, and others, who have followed his noble lead!

We are not very much enamoured of what are called philanthropic movements in general. The good spirit which prompts them often perishes in the mere act of forming an organization for itself to work with, and the organization itself becomes what Mr. Carlyle would call a "galvanized corpse," in which we see no beauty. But we believe in the work which the Metropolitan Drinking Fountain Association has undertaken. There is nothing questionable in its objects; nothing doubtful in its agency. Already the poorer population of London are drinking with delight of its bounty. On another page we give a list of no less than about SEVENTY sites on which the crystal cup is already sparkling, or is about to sparkle. And yet the Association has been at work for four months only!

In this day, when "bitter beer" is the continual cry of so many pompous mouths—when claret is giving its colour in so many cups—when champagne is "moving itself aright" in so many glasses—when Catawba wine with its taste divine, "dulcet, delicious, and dreamy," is filling so many rooms with its "sweet perfume"—in this day, we say, it may seem old-fashioned to put in a good word for mere water; and yet we do not hesitate to say that clear, pure, bright water still appears to us as sacred a thing as it did to Him who eighteen centuries since chose it as the best symbol of life which this world afforded. It is, indeed, the greatest physical gift of God to man. There is nothing we have which we would not sooner forego than water. How desirable, then, is it that a thing so excellent, and so abundant withal, should be placed within the reach even of the poorest poor.

We cannot undertake here to mention all the advantages which the new drinking fountains will offer to the labouring classes. We may say, however, that they will afford most welcome refreshment to the thousands of working people who are employed far from home—that thousands who even at home have no pure or sufficient water supply will drink at them

with gratitude—that most of those who do drink at them will imbibe a healthier fluid than the poor are commonly supplied with (the whole of the fountain water being carefully filtered)—that in times of prevalent disease these fountains will supply a most valuable and unstinted antidote—that the temptations and risks to which the poor are exposed in beer-shops and other like places will no longer be forced upon them—and that, as a consequence of all this, we may fairly anticipate a great reduction in the vices and crimes of the lower orders.

Experience has already gone a long way in confirmation of these statements. Let us quote a remark or two on this point from Mr. Wakefield's able pamphlet, "A Plea for Drinking Fountains," which we would strongly commend to the notice of our readers. The author says: "The fountains in Liverpool have been used to an extent exceeding the most sanguine expectations of their founder. The results are given in a tabular statement of the working of thirteen of the fountains erected by Mr. Melly. They may be generally stated thus: "in one day, of about 13 hours 8 minutes, 24,702 persons drank at 13 fountains; or, in other words, one person drank at each of the 13 fountains every 25 seconds for 13 consecutive hours; at one fountain as many as 3,340 persons drank in 12 hours, being an average of one drinker every 11 seconds; there were five other fountains at each of which above 2,000 persons drank; or, taking all the fountains, there was one drinker for every two seconds throughout a day of 13 hours." These registries were not all made, we are told, in summer; fewer persons, but still a considerable number, drink in winter. Allowing, however, for this Mr. Melly observes that "a calculation based upon a series of observations taken at different seasons, and in different parts of the town, by persons of perfect reliability, employed for the purpose, gives an average number of upwards of 1,000 drinking every day throughout the year at each of the 40 fountains scattered throughout the town and its outskirts." This would give 15 millions of persons who annually drink at the Liverpool fountains. And subsequently, in March, 1859, Mr. Melly writes that he is "quite sure that if 20 more fountains were judiciously placed here (Liverpool) both the new and old fountains would average 1,000 each the year round; that is, if Liverpool were adequately supplied with fountains they would be used 22 millions of times in the year! In other provincial towns, the experiment has been attended with like results.

If such have been the results in the provinces, it will be conceded, says Mr. Wakefield, that drinking fountains would be even more used in the Metropolis. The greater radiation of heat from a larger surface of buildings, less shade, more smoke and dust, and longer street distances, combine to make London a more thirst-exciting place than any provincial town. It is gratifying to state that the result of the experiment of the first drinking fountain erected by the Association in St. Sepulchre's church, on Snow-hill, fully confirms the above. This fountain is used about 7,000 times daily. It will be observed that this is more than double the number that drank at any one of the forty-three fountains erected in Liverpool. "As one of the many gratifying evidences of the practical usefulness of these fountains, it may be stated," says Mr. Wakefield, "that a gentleman who largely employs workmen in iron-works, in the town of Wednesbury, having recently erected fountains for his workpeople, says, that his manager has since observed an

"improvement in their habits, and regularity of attendance; attributable to their decreased use of beer, in consequence of the facility of obtaining pure water which the fountains afford." It would be difficult, he adds, to exaggerate the gratitude of the poor for these fountains, testified not only by the great numbers who flock to them, but by their many grateful acknowledgments in words and looks, as they quaff the pure cold water to allay their thirst.

We commend this subject to the regards not of London readers only, but also to those employers of labour throughout the country whom it is our privilege to address. Let us distribute freely to our mechanics and to our poor people that healthful and cheering fluid which Heaven has bestowed upon us so copiously, and we shall thus remove from them both the excuse for, and the occasion of, their worst sin.

THE CORT FAMILY.

PARLIAMENT has just voted £5,000 as a compensation to Mr. Barber for the mistake which was made in transporting him, and no one can possibly object to the arrangement. But it certainly seems strange that a Parliament which can show itself so just in a case of purely individual importance, can do nothing to cancel the effects of that great act—of villainy, one is tempted to say—by which the family of the great Cort was impoverished. Hear, reader, once more the simple tale:—"In bringing his inventions to perfection, Henry Cort expended a considerable private fortune, and even sacrificed one half of his patent rights, after which the remaining half, together with all his other property, works, trade, and contracts, were confiscated by the naval authorities, in 1788, for the debt of a partner (a Government servant who became a defaulter), not equal in amount to one-tenth of the sum afterwards produced from them. The family of this man, who thus nobly enriched his country to the ruin of himself, have, we most respectfully submit, higher claims upon the nation than any Government has ever yet recognised, although several Ministers of the Crown have, from time to time, aided them, none more promptly or more liberally than your lordship (Lord Derby) and Lord Palmerston; some, it is true, have received small pensions, and all have been participants of the very limited funds dispensed by the Royal bounty; but not one has been raised a single step from indigence, nor is one at this moment above want." This is the language of a memorial which has been signed by one hundred and thirty of the foremost manufacturers and men of science of this age and nation, addressed to two Prime Ministers in succession; yet nothing but donations from the Bounty Fund, infinitesimal pensions, and promises of suitable recompense hereafter, can be elicited from those noble-blooded personages.

But we must not be severe upon Ministers of the Crown when we find that those men of princely fortunes, the great ironmasters, who have been made princes by Henry Cort's inventions, and by them alone, show no gratitude to the man who made them. Not long since Mr. Fairbairn, moved by the long neglect which Henry Cort's children have had to suffer, offered £100 in the columns of the *Times* as the commencement of a subscription for the family. That generous and disinterested offer elicited, we are ashamed to say, not a single response. It is true that small subscriptions have of late years been given by a few ironmasters towards a Cort Testimonial Fund; but these deserve no mention side by side with Mr.

Fairbairn's noble letter, or in the presence of the great wealth which Henry Cort's inventions have created. The money value of the exported iron, iron machinery, and other articles made from iron, which was nothing in 1783, was, for the one year 1857, no less than £22,994,671 sterling; and the whole gain which this country has derived from the said inventions during the last seventy years, is estimated, in the "Encyclopædia Britannica," to amount to £600,000,000 sterling, as was stated in a Memorial signed by twenty-five of the most eminent authorities, supported by sixty Members of Parliament, including two Cabinet Ministers, presented in 1857 by Lord Stanley to Viscount Palmerston. This enormous addition to the wealth of the nation is quite independent of the collateral advantages resulting from the joint development of engineering, mining, agricultural, manufacturing, and every other branch of industry in which iron is largely employed. No ironmaster can therefore mention the £5 which he gave a year or two since as an excuse for not following up in a worthy spirit the lead which Mr. Fairbairn held out.

But the Cort family is even yet, we believe, destined to see brighter days. The whole of the facts of the case have been laid before Mr. Cobden, whose clear and energetic mind was at no loss to master its dark details, and whose generous goodwill has not failed to manifest itself on behalf of these aged people. He has promised, we learn, to aid their cause to the full extent of his influence, and we entirely believe he will do so. We wish to cast no slur upon any parliamentary personage who has hitherto interested himself on the behalf of—we will not say the Cort family, but the national honour, which has been stained by the treatment of that family. But we do say we would rather hear that Richard Cobden had whispered one syllable in favour of the cause, than learn that all the others whom we have named had agreed to promote it together. And this we say because we believe Mr. Cobden is a man of sounder sense and purer integrity than most of our great politicians. We say nothing here either in favour of or against his political principles; but we do believe him to be as sensible and reliable a man as there is in Parliament. He is consequently very influential in those counties in which he is best known, and we doubt not he will find means of using his influence for the furtherance of justice in the Cort case. It will indeed redound to the honour of Mr. Cobden, Mr. Fairbairn, and the friends of each of these gentlemen, as well as to the honour of Lancashire and Yorkshire, if the great manufacturers of those counties conduct this case to an honourable conclusion. They may well do so; for the inventions of Henry Cort, by giving us the iron of the steam engine, have benefited every branch of manufacture in which machinery is employed—the cotton trade to the extent of many millions sterling annually. We need not say what Cort did for Free Trade. He was really a promoter of that great modern movement; nay, he it was who taught us the secret of our own iron-producing power, and thus laid the basis on which so much of our modern trade and manufacture rests; while by aid of his great inventions the markets of Europe have been brought into instantaneous communication with Great Britain. All that Cort did was done, moreover, by means of native materials which were useless up to this time, and by the exclusive exercise of native labour.

It is stated that the design for the floating batteries intended to be used by the French on the Lago di Garda originated in England.

THE CASE OF HENRY CORT, AND HIS INVENTIONS IN THE MANUFACTURE OF BRITISH IRON.

BY
THOMAS WEBSTER, M.A., F.R.S., &c., Barrister-at-Law.
No. IX.

It can create no surprise that Cort's works at Fontley should have so soon acquired great notoriety, and be visited by the representatives or agents of most of the principal iron masters. Richard Crawshaw and James Cockshutt had visited, in 1787, "the little mill at Fontley," as the former designated it in a letter to Lord Sheffield's secretary. At that time Crawshaw was not forging more than ten tons per week at his Welsh works; he was too shrewd a character not to appreciate the labours of Cort, or to undervalue such a rival. He forthwith engaged with Cort for the erection of puddling furnaces and grooved rollers at Cyfartha, which were completed by his resident partner, James Cockshutt, under Cort's superintendence. The Cyfartha new mill (as stated upon the authority of Mr. R. Thompson) turned out 200 tons weekly of excellent bars with the same labour previously engaged in shingling and stamping out with the hammer (the according to our present ideas) insignificant amount of 10 tons weekly. Mr. Samuel Homfray, at the neighbouring works of Pendarran, was equally alive to the importance of, and not slow to appreciate, Cort's inventions; and, according to the statement in a letter from Mr. Cockshutt, borrowed of him the drawings of the puddling furnaces, the patterns of the rolls, and Cort's workmen for instruction in the operations; and contracts were signed for the payment to Cort of 10s. per ton of bar iron, as the licence due or royalty under his two patents.

The following letters, or portions of letters, which have been preserved, will be read with interest as contemporaneous accounts of, or throwing light on, the preceding:—

Kitley, 25th of 2nd month, Feb., 1789.

"RESPECTED FRIEND, HENRY CORT,—We are duly favoured with thine of the 19th inst., and in reply we are not quite so forward with our rolls as we expected by this time we should have been. It is our intention to have only one pair, and we have eight grooves in them beginning with a 3-in. one nearly round, and going less to a $\frac{1}{2}$ square. We have one welding furnace nearly ready, and it will give us pleasure if you can spare the man who has been used to the business to put ours in a way. It will give us additional pleasure if thou soon recovers from thy indisposition so as to be able to come up and see us make the first trial, and we are in the meantime,

(Signed) "WILLIAM REYNOLDS & Co."

"Cyfartha, April 5th, 1789.

"DEAR SIR,—I have delayed answering your last favour of the 8th past longer than I intended that I might advise you of the cargo of blooms and pig iron sent to Gosport, of which at foot you shall have an account. Since I have had any intercourse or exchange of letters with you we have made many careful trials with a stream of cold, after P. Onion's plan, in all of which T. Gales has been the principal workman. We have tried both Plymouth and Cyfartha metal, also sand-iron bottoms, both with and without blast, to which not only myself but my two colleagues also attended, that their opinion might be added in a joint report upon the business to our friend Mr. Crawshaw; and it is our opinion that no kind of change is produced from the use of cold air, as used by P. Onions. It does not bear the hammer better; it is not better in colour or texture; nor, in our

opinion, is it to be distinguished by any of these circumstances whether or no the cold air has been used. The iron bottoms occasioned such labour to the workmen that we could not continue them; but we found no advantage in doing, and P. Onions has been obliged to discontinue them, at least he covers them over with sand. Mr. Tait, some time ago, having much commended Peter's iron, I asked permission of Mr. Lewis to send down T. Cook. I had never seen but one heat worked, and I thought it probable they might have improved; but T. C. returned disappointed, and says they do not work near so well as we do. In return for this liberty, one of Mr. Lewis's men (Daniel Onions) was sent up immediately after to see what we were doing. He first saw a heat $2\frac{1}{2}$ cwt. weighed to Theodo. He attended the working; he saw one of the balls drawn out, and took a bit of the iron with him; it was all tough, and I think of a brighter colour than any I had seen. The yield was 20 lbs. blooms from 26 cwt. 1 qr. 21 lbs. He told me we beat them much in every respect, but told James Burch we made better dispatch and yield, but fell short of them in quality; and this they continue to give out. Our neighbour J. H. having determined to work under your patent entitled him to our best assistance. We first gave him the dimensions for his furnace, and let him have a man to built it; and we also spared him Thomas Gates for work, as I would much rather see the general success of the scheme than aim at any little exultation over him. The iron he makes draws and looks very well, and he allows himself that it draws sounder than their own, which is really true of so much as I have seen of it. But he has lately received but an unfavourable account of a small quantity which he sent into the north, of which his father complains that it will not bear slitting, but falls to pieces, and even that those rods which do not break he can shake it to pieces; yet he says the iron works well under the nailors' hammer, and makes handsome nails. You have had abundant trials of our iron; that which I saw slit at Fontley showed no inclination to fall to pieces, nor have I heard such a complaint from you. What S. Homfray may do now he has taken upon him the management, in the place of his brother, I cannot say; whether he will pursue the plan, or whether if he does, he will submit to his brother's proposals to you; he has often said otherwise. We have lately drawn out a quantity of your iron in which we find a good deal of vanity, though the blooms look equally well; but I am convinced it is by rolling the toughness is to be acquired, and your iron is particularly adapted for that purpose.

"The substance of my information to Mr. Gibbins respecting yield, &c., was that 30 lbs. of pigs would produce 22 lbs. of blooms, upon which I was inclined to believe something more than 20 lb. of bars would be made; but we had had little experience in drawing out, and would not speak certainly upon that subject; we had also made blooms with little more than the weight of metal in coals used, taking a furnace ready for charging; but this was with greater care than could always be used, and, therefore, a larger quantity must be allowed.

"Furnace building, 1s. 9d., including bricks; making and slinging blooms, 20s. per 22 lbs. This letter was dated January, '88, since then I have not heard from them, but I believe Mr. Crawshaw had, by whom you will have been informed what passed from our late experience in drawing. We find it requires more than 22 lb. of blooms to a ton. of bars. I am desired to send a ton of our bars made after your process to Stourton, which I am inclined to do.

(Signed) "JAMES COCKSHUTT."

"Plymouth blooms are marked with two strokes of white lead; Cyfartha with one; Plymouth pigs without any mark; the Cyfartha has one stroke of white lead; other particulars you have heard from H. Charles."

On the 11th of March, 1789, Messrs. J. Homfray and Co., of Pendarran, write as follows:—

"DEAR SIR,—Am much obliged for yours of the 19th of February, and the other side send you an account of our performance." The letter, which is mutilated and imperfect, contains the following passage:—"So satisfied myself about it that I shall provide no more blast than is necessary for a blowing a furnace in a new concern I am about establishing upon these mountains, supposing all blast in future as unnecessary in manufacturing bar iron. The new forge at Cyfartha, upon your plan, is a noble thing, and does great credit to those gentlemen there; they are driving it forward with great spirit, and will constantly turn out about 30 tons a week of blooms; they are now drawing some for London. Your rolling mills, not only for these blooms, but for all * * * makes them beautiful iron. I have been to Bristol since, but could not meet with M. Trueman Harford to hear his opinion, but found from the iron weigher that 15 cwt. of it had been sold; and one smith had told him that it worked very well, and punched famously; this we find to be the case in our own shops. The Port iron will be slit at Stourton, and worked under my father and brothers Sam. and Tom's own eye, who are both very anxious for its well-doing, and impatient for its trial. I have no doubt * * Mr. Cockshutt desires to join me in remembrance."

"February 21, 1789. Pigs del patent furnace 3 tons 13 cwt. 3 qr. 7 lb produced blooms, 2 tons 8 cwt. 1 qr. 29 lb.; bars, 2 tons. 1 cwt. 1 qr. 20 lb.

"Takes 1 ton 10 cwt. 1 qr. 23 lb. pigs to make 20 cwt. blooms, and 1 ton 15 cwt. 2 qr. 17 lb. pigs to 20 cwt. bars.

"Chaffery takes 1 ton 3 cwt. 1 qr. 19 lb. blooms to make 20 cwt. bars.

"Coals used in the furnace, 6 tons 12 cwt.

The judgment of the most competent persons was unanimous in favour of the merits of Cort's invention; the trials in the public Dockyards,—the condition of the Navy Board requiring the use of Cort's iron only, were conclusive as to the success of the process. The acts and opinions of the individual ironmasters, could leave no doubt as to the enormous value of the new processes; they took or entered into contracts for licences upon terms freely and liberally conceded on both sides; they expended large amounts of capital for the erection of works, which in a few years would have produced bar iron sufficient to yield ample remuneration to Cort, and a princely fortune for his thirteen children. Cort and his results stand unparalleled in the history of invention and inventions as a case in which the merit of the invention should be universally conceded almost immediately after its announcement, and the rights of the inventor should be so universally acquiesced in by the trade, some of whom were the owners of or interested in prior inventions.

The sequel will disclose a case unparalleled both as regards the character of the transactions and the consequences to the individual concerned.

The *Mersey*, 40, screw, Capt. Caldwell, C.B., will shortly make a trial of her altered screw, at the measured mile in Stokes-bay; the leading corner of each blade of the screw having been cut off, in consequence of the results obtained from the late experimental trials of the *Doris*, as affecting the ship's vibration.

WHAT IS TO BE DONE WITH OUR SAILING SHIPS OF WAR?

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."
London, August 17, 1859.

GENTLEMEN.—My mind has been occupied for some time with the consideration of a mode of rendering our sailing ships effective as ships of war; but as the subject involves questions which can only be satisfactorily answered by seamen, I request the favour of the publication of the following thoughts concerning it, in the hope that some of the many naval gentlemen who appear to take an interest in a mechanical journal will endeavour to throw light upon it. Omitting those sailing ships now in process of conversion, those which have been appropriated as depots of various kinds, and all whose age exceeds forty years, we have still a fleet of at least 80 line-of-battle ships and frigates which have not yet reached the age of decrepitude. Their ages, reckoning from the dates of launching, are as follows:—Seven line-of-battle ships of from ten to twenty years; three between twenty and thirty years, and twelve between thirty and forty years. Of frigates carrying between 40 and 50 guns, thirteen of from ten to twenty years, seven between twenty and thirty years, and twenty-two between thirty and forty years, and of smaller frigates, nine of from ten to twenty years, and eight between twenty and thirty years. How many of these may be the victims of premature decay I know not, but that age alone has not incapacitated them for service, supposing them to have undergone the ordinary periodical repairs, will appear from the consideration, that of the ships whose soundness of constitution has justified their conversion into steam ships, the *Nelson* is 45 years of age; the *Neptune* 27; the *Royal William*, the *Waterloo*, and the *Rodney* 26. Supposing, then, that the majority of these ships are too old, as they certainly are, to justify the expenditure of large sums in lengthening them to receive engines, and are yet in sufficiently good condition with moderate repair to take the sea as sailing ships, I propose to inquire whether they could, under the altered circumstances of naval warfare, be made efficient fighting ships without the aid of steam power.

It is pretty generally acknowledged, that so long as a screw steam-ship has the power of lying at pleasure across the bows or the stern of a sailing ship, and sweeping the whole length of her decks with a broadside, the sailing ship must be over-matched, although greatly superior in strength to her adversary. And I do not doubt that in the event of war with a maritime power, all the sailing ships now on Foreign Service would be on this account instantly recalled.

This disadvantage would be completely removed if the sailing ships possessed the means of turning or changing their positions without the aid of the sails or rudder; and I do not see that in other respects they would be much inferior to converted ships.

Let us suppose a 90-gun ship to be lengthened to receive engines of 450 or 500 horse power at a cost of £50,000 or £60,000. It would seem, judging from ships like the *Algiers* and *Hannibal*, that we could not expect to get more than nine knots per hour out of her. In the "*Nile*" engines of 500 horse power do not give seven knots. Now, it is difficult to see what advantage such a ship would possess in a contest with the *Shannon*, say, of 50 guns, and having a speed of nearly twelve knots per hour, which she would not have possessed had she remained a sailing ship, and been fitted with the means of changing her position which I have suggested. Her conversion has only made her far more vulnerable; her engines, her screw, and her weak rudder-post are all vital points, and are all exposed to fire. Her screw is, moreover, constantly liable to be fouled by the wreck of her own spars, or of those of an enemy. It cannot be doubted that there are some circumstances, especially those connected with the evolutions of a fleet, under which the steam power would be very valuable, but we cannot doubt, on the other hand, that the vulnerability I have pointed out deserves serious consideration—far more serious consideration, I believe, than it is likely to receive until we have learned the bitter lessons of experience.

I am not desirous of proving that the sailing

ship may be made superior to the slow and vulnerable screw ship for war purposes, but I am most certainly of opinion that these sailing ships of ours may be made available for service on foreign stations, so to avoid the great expense connected with the constant use of auxiliary steam-power, and to augment the fleet for home defence by those steam-ships which are now wasting their 60 or 70 tons of coal per day in doing what could be as well done by sailing ships. There would be this advantage, too, in the plan proposed, viz., that nearly every ship fitted in this way would be clear gain in comparing our strength with that of France, as she has but few sailing ships left.

I have stated all this with hesitation because I do not feel competent to decide upon the questions involved; but this I say confidently, that if the possession of the means of turning without the aid of rudder or sails would do what I have supposed, it may be cheaply and quickly obtained. Nothing more is necessary than to cut a hole in the deadwood to receive a screw capable of motion in a vertical longitudinal plane by means of manual or other power on board. The amount of power required may be readily ascertained by comparison with the rudder. A ship would have good steerage way with a speed of six knots; in other words, a rudder moving through the water at this speed would certainly encounter sufficient resistance to turn the ship. But as the rudder is never inclined at a greater angle than 30° to the line of the keel, the normal or effective velocity of the water on the rudder would only be three knots. If, therefore, a screw of sufficient size is made to revolve fast enough to give a velocity in advance of three knots, it is likely to do more towards turning the ship than a rudder hard over, because the thrust is more direct. Now, a screw ten feet in diameter, two feet long, and with twelve feet pitch, could be easily fitted in a frigate without weakening her or diminishing her stowage. Such a screw would, with twenty-five revolutions per minute, move through the water in advance with a velocity of three knots per hour. The indicated horse-power corresponding to this would be, if the screw were under the same circumstances as the propelling screws, about 7½. It may, therefore, be fairly assumed that nine or ten horse-power, applied by means of capstans, or if it were thought desirable, by a small donkey-engine, would be sufficient to turn a 50-gun frigate as rapidly as she would be turned by her rudder with a steerage way of six knots. Such a screw would be ten or twelve feet below the water, and entirely within the ship, so as to offer little resistance to motion. In the section which accompanies this letter the screw is shown in the horizontal position, which, being that of least resistance, would always be assumed when the vessel was in motion, supposing the screw to be allowed to move freely. The only resistance of any consequence caused by the introduction of the apparatus would then be the negative and positive pressures at the fore and after ends of the aperture. These might be reduced if it were found desirable by hanging slight metal shutters over the upper portion of the aperture. Some of your readers may remember that a proposition was made some fifteen years ago by a Mr. Foulerton, master mariner, to fit all kinds of sailing and screw ships with an apparatus of this kind to assist the vessel in stays, and to enable her to manœuvre after the loss of the rudder. It was entertained by the Admiralty, and a screw was fitted by Mr. Foulerton in the St. Lawrence frigate. As it was only 3 feet 6 in. in diameter it failed, as might have been expected. All the reasons for its adoption urged by him upon the Admiralty still exist, and with the special one I have here endeavoured to point out.

I am, Gentlemen, your obedient servant,

A NAVAL ARCHITECT.

BOYDELL'S TRACTION ENGINE.

DURING last week the capabilities of this admirable road locomotive were publicly tested in Hyde Park previous to the engine and its train of waggons being despatched to Bombay, in accordance with the wish of the Secretary of State for India. The engine is perfectly under control, even for the sharpest turnings of ordinary streets, and easy both in ascent and descent of steep inclines. This endless rail acted with the most perfect satisfaction, quite bearing out what has been before stated, that the engine could not only travel over the worst roads, but that the roadway itself is actually improved by the equal and broad compression of the rails. The engine can with ease draw from 60 to 70 tons along ordinary turnpike roads at the rate of four miles per hour. Attached to the machine were five powerful waggons specially made for the purpose by Cresskill, and all of which, by removing a pin or pivot from between the two leading wheels, are enabled to follow every turn of the engine, with a serpent-like movement, which gives the utmost freedom and flexibility to the whole convoy. More than once the whole train turned in less than half its length, and that, too, in passing over grass and uneven ground. The indentation made by the passage of the wheels was certainly no more than would have been made by an ordinary coal wagon. 160 soldiers of the Guards were in attendance and rode in the waggons, and with this load the whole train was taken easily across the level parts of the Park at the rate of six miles an hour. The result of the trials were in the highest degree satisfactory, and seems to leave no doubt whatever that over the rough roads of India during the summer season, when the rivers are dry, the engines will be of the utmost service in facilitating the transmission of merchandise. For military purposes, such as getting up guns and siege stores, an engine of the kind would prove an invaluable auxiliary. Two have been ordered for the Pasha of Egypt for the purpose of traversing the deserts with caravans, and before long doubtless many more will be sent to India.

JENSEN'S MARINE ENGINE GOVERNOR.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—Will you allow me to offer a few remarks on an invention of Mr. P. Jensen, as described in your columns, for regulating the speed of marine engines during severe gales. The inventor proposes, by means of self-acting machinery, to shut off the steam at the moment the water descends from under the paddles; then to admit it into the engines as soon as the waves arise to their ordinary level. The arrangements, it must be admitted, are very simple, and the principle will probably appear very plausible to many persons. But there is no difficulty in demonstrating that the arrangements proposed would fail to accomplish the object in view. Mr. Jensen has evidently lost sight of the fact that, when engines have attained their full speed, each stroke of the piston becomes independent of the action of the steam; and, consequently, that the shutting off of the steam would not instantaneously diminish the speed of the screw or paddles. The only result that would be obtained by adopting this invention, would be to check the speed of the engines at the moment when great power would be required; that is, when the waves would strike against the paddles, causing a deeper immersion. The steam, it is true, would be admitted at that moment, but this would not increase the speed of the engines until the moment when greater speed would be more than useless; for, by the time the steam would have given a full impetus to the engines, the paddles would, probably, be again whirling in the air. Every engineer who has watched the working of marine engines when sailing over a heavy sea, well knows the inconveniences and dangers of the present arrangements; but it is far easier to see the extent of the evil, than it is to provide an efficient remedy. When the screw and paddles are combined in the same

vessel, the evil complained of will be diminished to some extent, provided all the engines are connected. The screw and paddles would act tolerably as governors, somewhat on the same principle as fly-wheels in stationary engines, and I imagine that principle might be adopted in vessels with engines of not less than 800 horse-power, provided the screw shaft could be efficiently connected with the paddle engines. Probably the result would be that a high speed could be maintained while sailing over a heavy sea, with a head wind, without having recourse to an increased consumption of fuel, as at present. If I am wrong in these surmises, probably some of your correspondents will set me right.

I remain, Gentlemen, very respectfully,

JOHN DE LA HAYE.

Perth, August 16th, 1859.

IMPROVED RIFLE FIRE-BRAND.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—The rifle-brand, charged with phosphorous dissolved in bisulphide of carbon, which I lately successfully tested at Chatham, with the sanction of his Royal Highness the Commander-in-Chief and the late Secretary for War, was so constructed that its neck was broken on striking; loose hanging canvas, when the liquid spread on the canvas and immediately set it on fire. My present improved brand has a tube of glass charged with the liquid placed within. It is then closed in front with a plug of lead. On firing the rifle the glass tube breaks by the jar of the exploded charge. The liquid is diffused in the interior of the brand, and cannot immediately escape from it; but after a few minutes it will percolate through the sap pores of the wood, and burst into flame. This brand is therefore well adapted for setting fire to long grass, bushes, weeds, &c., that cause no shock to the fall of the brand, and will set fire to the vegetation all around a hostile battery of artillery whenever it moves.

I am thus particular in describing its usefulness, because I sometime ago read a speech in the public papers by his Royal Highness the Commander-in-Chief, wherein he stated that he should be glad to receive information on military matters from all persons qualified to give it; and also because when I had the honour to attend a Lecture at the Horse Guards more than a year ago, his Royal Highness was pleased to say, "We ought to be much obliged to you."

I have found that after using a leaden shell charged with the liquid, when all the liquid appeared to have burned out, on melting the used shell in an iron ladle, a portion of the phosphorous, which remain on the lead in a state of incrustation, continued to burn for some minutes. This proves the extraordinary "vitality of the liquid fire."

J. NORTON.

Rosherville, July 30.

P.S.—Colonel Sandham, R.E., commanding at Brompton, Chatham, informed me that a report would be made to the War Department on the result of my practical experiments at Chatham. Several months have now passed, but I have not yet heard of the nature of that report. I am, however, ready to repeat the experiments at any time or place required.

J. N.

Some months back Mr. J. Bailey Denton, of Stevenage, published some observations in anticipation of the effects of the drought of last winter in reducing the water supply of the present summer and coming autumn. His anticipations are now, he says, being realized, and many are the villages and wide are the districts in which the inhabitants are suffering from the want of the first essential of health and comfort, and he again calls the attention of our legislators and the larger landed proprietors, who are returning to their estates in the country, to the importance of providing water in the villages of the rural poor. He suggests that means be found to concentrate and preserve the drainage and surface water which runs to waste during the non-evaporating months of winter and spring for use in the summer and autumn in those localities where from soil and height there is no constant supply.

FREE DRINKING FOUNTAINS.

In our leading columns we have drawn attention to the beneficent work of the Free Drinking Fountains Association. We here propose to show what mechanical arrangements the Association has adopted for the efficient and economical carrying out of its plans. The simplicity of these arrangements (which are shown in the sectional view Fig. 1 of the annexed engravings) are obvious, and call for little remark, if we except the application of a filtering medium in an air-tight cylinder in connexion with the main supply pipes of the water companies, by means of which a large amount of pressure will be obtained to force the water through the filtering medium. The construction of this cylinder with a convex bottom permits most of the organic impurities to fall by their own specific gravity, thus reserving for the filtering medium only the action of stopping the more minute organic impurities, with those held in solution. The flushing pipe is always a ready means of cleansing the cylinder cistern. The ball-cock cistern shown is rendered necessary by the requirements of the Water Companies, and will in some measure regulate the pressure. The filtering medium has been prepared upon principles approved by the Association. It will be inclosed in, or will itself form, a second cylinder containing animal charcoal, through which the water must pass, previously passing in the one case first through a porous and charcoal stone imported from abroad, and suggested by Mr. Jackson, the Secretary of the Association, and in the other case, first through a filtering substance manufactured expressly for Messrs. Wills, of 12 Euston Road. These filters for the present will be applied inside the air-tight cylinders, and the result it is hoped will support the strong opinions expressed of their efficiency. The cylinder-cistern may be applied to either Standard or Mural Fountains, or in case their structure will not admit of insertion, the same arrangements can be made underground.

The Association having engaged to erect a drinking fountain in the Crystal Palace grounds, the company selected the design. This fountain, shown at Fig. 2 (by Messrs. Wills, Bros.), which we have had carefully engraved, can be constructed of bronze or bronzed iron, and the vase may either be of the same materials or of marble. This design, although occupying but the smallest space with the greatest strength, will allow of nine persons drinking at one time.

The water supply for drinking fountains will, it

oped, be provided by the liberality of the companies, as *three* have already consented to; but until a memorial, which the Association has now prepared to be sent to the general meeting, can be answered, no exact statement as to what can be made.

The following list of sites may be acceptable as being the number of fountains which the Association has erected, or is now under engagement to erect, having in four months from the date of the opening received through the donations of private persons and contributions from the local authorities, the funds and the control over sites necessary for this encouraging commencement of great work proposed, viz., to erect not less than four hundred fountains in the metropolis:—

Fountain at Snow-hill, Mr. Gurney.
 Emerson-street, Bankside,
 Upper Ground-street,
 Triangle, Union-street, Borough,
 Rowland Hill's Chapel,

Five in connection
 with St. Saviour's,
 Southwark.

7. Islington-green,
8. Holloway-road,
9. Lower-road,
10. Liverpool-road,
11. Caledonian-road,
12. Regent's-circus, Oxford-street, Mr. Gurney.
13. Bethnal-green, in front of St. John's Church, with Mr. Link (now opened).
14. Marylebone Workhouse wall, with a lady (ready for opening).
15. Stepney, with Rev. J. Kennedy.
16. Bermondsey, Mill-lane, with vestry (nearly ready).
17. Victoria-gate,
18. Pickering-place,
19. Alie-laide-place, Regent's-canal,
20. Paddington-green,
21. Sloane-square,
22. Near Pier,
23. Peter-street,
24. Broad-street,
25. Great Marlborough-street,
- 26.
27. Tower-hill, opposite Mint, with Whitechapel Board of Works.
28. Newington-causeway, with Mr. Dunn.
29. Adelaide-place, London-bridge, with Provident Institution.
30. Endell-street, with Mr. Langdale (now open).

Five with St. Mary's, Islington
 (one opened last week).

With Paddington
 Vestry.

With Chelsea Vestry.

With St. James's, Westminster.

31. Victoria-road, near Palace-gardens.
32. Strand, with Mr. Hanbury, M.P.
33. Mother Red Cap,
34. Junction-road, Kentish-town,
35. Southampton-arms,
36. Brighton-street, corner of Cromer-street,
37. Euston-square,
38. Tottenham-court-road,
39. The Brill, Somers-town,
40. York and Albany,
41. Pancras-vale,
42. Brecknock-arms, Camden-town,
43. Goldington-crescent,
44. Gray's-inn Hospital,
45. Hampstead-road,
46. Cumberland-market,
47. Horseferry-road, Westminster, Mr. Stafford.
48. Westminster-bridge-road.
- 49.
- 50.
- 51.
- 52.
53. Cannon-street-road,
54. Chigwell-hill,
55. Highgate-hill,

- 57.

With St. Pancras
 Vestry
 and
 private
 persons.

With Mile-end, Old-town, Vestry.

With St. George-in-the-East.

With Committee at Highgate.

58. At the Royal Exchange, Metropolitan Drinking Fountain Association.
 59. Waterloo-road.
 60. In railings of St. Saviour's Church, Southwark.
 61. In Tooley-street.
 62. Near Marble Arch, with Baron de Bliss.
 63. Rosemary-lane, with Miss Barber.
 64. Near railway station, Putney.
 65. Near Arsenal gates, Woolwich.
 66. Landing-pier, Lambeth, Rev. J. Lingham.
 67. New-cut, Lambeth, with Sir M. Peto.
 68. Crystal Palace, Sydenham.
 69. East India Dock Gates, Poplar (opened last Thursday).
 70. Moor-street, St. Giles (with working men).

Several of these will now be opened each week to the public.

The objects which a street drinking fountain should, in the opinion of the Association, attain, and the conditions of their attainment, are as follows:—They are—

1. To yield a small stream of continually flowing pure and cool water, most easily accessible to the greatest number of people.

2. The Metropolitan Fountains Association has decided, in accordance with the opinion of eminent medical officers, to increase the purity of the water by a process of re-filtration, and this must be done in the fountain itself; therefore, each fountain must be so constructed as to contain a filter, which shall be easily accessible at all times.

3. In accordance with the inflexible requirements of water companies, each fountain must be also provided with a ball and cock cistern, as this operates to destroy the force of the water, consequently it must be placed above the point of the water in the cup.

4. The pipes, filter, &c., must be insulated, so as to preserve the water from the extremes of heat in summer and cold in winter.

5. The fountain must occupy the least possible space. The necessity of this consideration is obvious, seeing that most of these fountains are intended to occupy space in the greatest thoroughfares of the metropolis.

6. The upper structure of the fountain should as little as possible intercept the street view.

A number of designs have been submitted to the Association, and from them several have been selected. The best of them were engraved in the *Builder* for August 6, to which we would refer our readers.

By the kindness of Mr. Smithies, the esteemed editor of the *British Workman*, we are ourselves enabled to present in Fig. 3, a new and splendid engraving of the fountain recently erected by the New River Company, prior to its appearance in that publication; and by the favour of the same gentleman, we are also enabled to illustrate the Liverpool fountain, Fig. 4, in conjunction with which a cattle trough and dog trough have likewise been erected as shown. These admirable wood-cuts speak for themselves.

For a statement of the rapid progress which the drinking fountain movement is making in the provinces, we must refer to the various detailed statistics that from time to time have been published.

Literature.

Rifled Ordnance. Fourth edition, revised and enlarged. By LYNALL THOMAS, F.R.S.L. London: Published by J. Weale, 56 Holborn. 1859.

THIS volume, in its former editions, in which it was published anonymously, was noticed with some favour in our columns. Its authorship is now acknowledged by Mr. Lynall Thomas, who has of late years had several improved forms of ordnance and projectiles under trial at Shoeburyness with very good results, and who has also carried out numerous experiments on gunnery privately and at his own expense. To the work in its present form—the sub-title of which is “A Practical Treatise on the Application of the Principle of the Rifle to Guns and Mortars of

every Calibre”—Mr. Thomas has added a full reprint of the paper contributed by him in December last to the Royal Society, on a New Theory of the Initial Action and Force of Fired Gunpowder, a lengthy abstract of which was published in the *MECHANICS' MAGAZINE* for June 3rd, page 360.

The subject discussed in this volume is a modern one, and has not hitherto gained much attention from authors competent to treat of it accurately. The great merit of Mr. Thomas's treatise is due to the fact that he has not confined himself to mere theoretical inquiries, but has taken considerable pains, first to ascertain facts experimentally, and then to elucidate them by reference to mathematical considerations. The order in which he proceeds is as follows:—1, general remarks on rifled cannon and projectiles; 2, the turn of the rifling; 3, the influence which the size of the projectile has upon the turn; 4, rifled projectiles; 5, the grooves and increasing spiral; 6, the comparative advantages attending the employment of rifled and smooth-bored guns; 7, the range of elongated projectiles; 8, experiments in gunnery; 9, the nature and action of fired gunpowder. As an original and valuable treatise on a very important subject, we warmly recommend the volume, although we cannot undertake to assent to all the principles laid down in it.

The following extract from the preface will serve to illustrate both the style and the capabilities of the author:—

“My attention has recently been directed to a statement made by Sir W. Armstrong at the United Service Institution, and reported in the *MECHANICS' MAGAZINE* for June 3rd of this year, to the effect that elongated projectiles have a greater range when they are fired in the air, than they would have if they were fired in a vacuum, or non-resisting medium. This statement bears at first sight so much resemblance to certain opinions which I have hazarded myself, that I take the opportunity afforded by a preface to make those observations with reference to it, which I was precluded doing in the proper place, from the circumstance of the sheets being already in the press. Sir W. Armstrong's remarks (as reported) are as follows:—‘In a vacuum the trajectory would be the same whether the projectile were elongated or spherical, so long as the angle of elevation and the initial velocity were constant; but the presence of a resisting atmosphere makes this remarkable difference, that while it greatly shortens the range of the round shot, it actually prolongs that of the elongated projectile, provided the angle of elevation do not exceed a certain limit, which in my experiments I have found to be 6°. This appears at first very paradoxical, but it may be easily explained. The elongated shot, if properly formed, and having a sufficient rotation, retains the same inclination to the horizontal plane throughout its flight, and consequently acquires a continually-increasing obliquity to the curve of its flight. Now the effect of this obliquity is, that the projectile is in a measure sustained upon the air, just as a kite is supported by the current of air meeting the inclined surface, and the result is, that its descent is retarded, so that it has time to reach to a greater distance.’ The above remark that the air ‘actually prolongs the flight of elongated projectiles,’ requires to be considerably qualified. This effect may perhaps be produced under certain circumstances, as, for instance, when the weight or the length of the projectile is great in a certain proportion to its diametral surface, when the velocity is limited, and other circumstances, which I shall allude to directly. Although Sir W. Armstrong may have remarked this peculiar effect in his 32 lb. or 18 lb. elongated projectiles (in the same manner as I noticed it myself with a 32 lb. projec-

tile of three diameters in length) I should hardly think that he had observed it in the case of elongated projectiles of smaller diameter, unless they were fired with a lower velocity than usual. In the chapter ‘On the Range of Elongated Projectiles,’ the reader will observe that I have not gone quite so far as to assert that long projectiles actually have their range prolonged when fired in the air; I have merely hazarded the conjecture that, under certain circumstances, such might possibly be the case. It cannot be positively asserted as a fact, until we know precisely what initial velocities these projectiles really acquire. I suppose that it might be true, from the circumstance of finding that the ranges of long projectiles of a certain size and form, varied in a greater degree (with the elevation) than they would do in a vacuum. The full explanation of the manner in which the resistance of the air tends to lengthen the flight of a long projectile, may be seen as follows:—When a round projectile is passing through the air, the whole resistance to its flight* is in the direction of the tangent to the curve; but when a long projectile is used, a different result is obtained. For, in consequence of the well-known laws of hydrodynamics, that when a solid body strikes obliquely on a fluid mass, the resistance will be perpendicular to the surface of the solid, the resistance on the surface of an elongated shot will no longer act in the direction of the tangent to the curve of flight; but the resultant of the pressures on the fore end and the under side will act in a direction above the tangent to the curve, so that although the velocity of the projectile is diminished, it will be made to describe a path rather less curved to the horizon than it would otherwise have done. Hence in certain circumstances, as when the elevation of the gun is not very great, the range may be prolonged. It will be noticed that Sir W. Armstrong considers that to be a properly formed shot of which the axis remains parallel to itself during its flight; but I am convinced it will be found that a preferable form of shot will be one that has the centre of gravity thrown forward, so that the shot will remain approximately a tangent to its trajectory throughout its flight. In this case the loss of velocity will be much less than in the former, and at the same time the obliquity to the trajectory will be sufficient to call into play the sustaining power of the air. A projectile which maintains its axis parallel to itself might have a certain advantage when the gun has little or no elevation, because the obliquity to the curve of flight would not then be so prejudicial to the velocity of the projectile, and the whole of the pressure upon its under surface would tend to sustain its flight; but the time of flight, in this case (unless the gun were placed on an eminence), would be too small to admit of any great advantage being thus obtained. When, however, the angle of elevation is high, the increasing obliquity to the curve of flight tends to diminish the velocity more than to retard the descent of such a projectile; and its curve of flight and range are, in consequence, diminished. Hence the effect which Sir W. Armstrong remarked in his experiments; that the prolongation of flight alluded to was only observable when the angle of elevation was below 6°. Sir W. Armstrong's concluding sentence, that ‘its (the projectile's) descent is retarded, so that it has time to reach to a greater distance,’ could hardly, I should think, have been carefully considered before it was uttered; for every person familiar with the theory of the motion of projectiles will see that by diminishing the velocity of a projectile after it has passed the apex of its curve, its time of flight is lengthened, whilst its range is, on the contrary, diminished. Further experiments will be required for ascertaining whether the forward position of the centre of gravity conduces as much to precision as to great range. Of the latter there can be no doubt; and I believe it will be found that, at the higher elevations, projectiles constructed in this

* This is independent of the unequal action of the air on opposite sides of the shot, caused by its rotary motion!

nanner will achieve both greater range and greater accuracy than any other.*"

The author of this volume has been fortunate enough to be present, with the consent of Sir W. Armstrong, at several trials of the Armstrong gun at Shoeburyness. Like ourselves he is not disposed to view that weapon with unqualified approbation, or to consider it by any means a final success in the art of gun manufacture. That it has excellent qualities neither he nor we deny; but that it is better suited for the wear and tear of actual warfare than all others we are not by any means prepared to admit. As the subject is of the utmost importance we extract the following remarks from Mr. Thomas's pages on this weapon:—

THE ARMSTRONG GUN.

"The great merit of the Armstrong gun appears to consist in an admirable combination of certain approved principles rather than in the adaptation (except, perhaps, with regard to the manufacture of the gun) of any positively new invention. So happy a combination, however, could only result from numerous experiments conducted by a person possessing great mechanical skill, and a considerable knowledge of the science of gunnery. The chief noticeable points in which this gun differs from those in ordinary use, are the metal of which it is constructed, and the breech-loading principle upon which it acts. With regard to the first of these points the success of the Armstrong gun has placed beyond a doubt the fact that wrought-iron and steel are admirably adapted for the construction of rifled field-pieces and guns of a medium size. This, in itself, is an important fact. But as gun-metal is also well adapted for field-pieces, the question whether it would be advisable to construct the smaller kind of guns of the above metals will depend very much upon the time and expense which must necessarily be employed in their construction, but should the construction of guns capable of throwing elongated shells, of a weight equal to that of the heaviest shot now in use, and upwards, be attended, as it probably will, with the same successful results, the employment of these metals—at least for large rifled cannon—will be imperative. The breech-loading principle has, I think, but few points to be remarked in its favour, compared with what may be urged against it. In this case, however, the combination by which the efficiency of the projectile is obtained is dependent entirely upon it. The great accuracy and range obtained with the Armstrong gun are startling from their novelty only; for as yet the rifled cannon is but in its infancy; and although the greatest possible praise is due to Sir W. Armstrong for the great ingenuity, as well as for the superior mechanical and scientific knowledge which he has displayed in the construction both of his gun and his projectiles, I am nevertheless fully persuaded that equally good results will be obtained with a combination of a much more simple and inexpensive character. The expenditure of time and labour which would be necessary to keep a large number of breech-loading guns continually in a fit state for service, both when stored and in use, must prove a great

obstacle to their general employment. Their general efficiency in action also has yet to be tested. An additional obstacle presents itself in the fact that these guns would be very difficult to procure in a sufficient quantity on an emergency. The constant improvements which are likely to be made in breech-loading pieces should also render us cautious about adopting any one method in particular until its superiority has been thoroughly established in actual service. Breech-loading guns, unless of the simplest construction, must always be objectionable in action. It may be an easy matter enough for well-trained men, under the immediate superintendence of a number of scientific officers at Shoeburyness, to fire so many rounds a minute; but would this be so in action? A system of breech-loading, which a man of common capacity cannot learn and retain after ten minutes' teaching, and one which causes the employment of detached pieces of metal; any, in fact, which requires more than two simple movements, one to open and one to close the chamber, is open to objection. If it is considered necessary to employ breech-loading pieces, they ought to be made to act with a movement which a man can perform mechanically, as a soldier loads his musket or a sportsman his gun, without having to think over it. Great care must be taken, with guns upon this principle, that no escape of gas is allowed; otherwise, the men between decks in a ship, or in a casemated battery, would be stifled in working them; not to speak of the loss of power occasioned by it. Regarding the Armstrong gun as a scientific engine or machine for the projection of an elongated shot, it is a *chef-d'œuvre*; the accuracy obtained with it is remarkable. This is partly due to the delicacy of the sights (which are so arranged as to allow for the lateral deflection), and to the absence of all recoil. If the maximum results attainable with rifled cannon depended entirely upon the combination employed in this case, we might safely assume that no other nation could produce a weapon to surpass it; it would, however, be presumptuous to assert this—in fact, both at home and abroad, results nearly approaching, if not equal to it, have been already obtained by much simpler means; and if a hostile nation could produce half-a-dozen guns to our one, it would be a matter for serious consideration whether it would be to our advantage to employ guns constructed on this principle or not. As it is, other nations are already fully equipped with rifled cannon, whilst we possess some dozen experimental guns only. Even allowing that the rifled cannon of foreign nations are not equal to the two or three specimens of the Armstrong gun which we possess, we are by no means certain that they are not better adapted to the purposes of war. So much has yet to be learned respecting rifled cannon that no one can assert, at present, that the Armstrong gun—untried as it is—is really the best suited in every respect for actual warfare. Moreover, if we confine ourselves to guns constructed upon this principle, we can only have two hundred of them at the end of a year. But supposing that in six months' time we are engaged in a great European war; and supposing, further, that the Armstrong gun be found in actual service to fail in achieving all that has been anticipated from it, what are we then to do for rifled cannon? Surely some such method as that which I have suggested might be adopted, in order by utilizing the principle of the rifle to place us at once on an equal footing with other nations, without prejudice to our finally adopting that description of gun which is found by experience to be the most suitable for practical purposes, whether it be the Armstrong or any other. Perfect accuracy is, no doubt, highly desirable; but there are so many circumstances which must arise, in actual warfare, to preclude the possibility (except under very peculiar circumstances) of its attainment, that it is extremely questionable whether it is worth while sacrificing other important objects in attempting to acquire it. A difference of a few feet in the deflection, in

a range of a couple of thousand yards or so, cannot surely be of so much importance as to have a gun of simple construction and easily worked."

We should be doing very imperfect justice to the author if we failed to state that his work is much more than a medium for recommending a particular form of gun and projectile of his own invention. He does recommend improvements of his own, it is true; but these are by no means the staple material of the volume. It may with fairness be described as an essay towards a discussion of the nature of rifled cannon generally, and the principles involved in their construction, together with an endeavour to urge the Government to undertake a full and scientific inquiry into this much neglected subject. In working out these great objects the author communicates much original and valuable information, but he never loses sight of the fact that no work can at present be more than an essay, or an attempt to approach the truth of the matter. Viewed in this light, his work is a very praiseworthy and instructive one, and no student of gunnery or gun-construction, whatever his knowledge or experience may be, should think of leaving it unstudied.

Wool and Woollen Manufactures of Great Britain: a Historical Sketch of Rise, Progress, and Present Position. SAMUEL BROTHERS. 1859. London: Piper, Stephenson, and Spence, 23 Paternoster-row.

This book is printed on such very superior paper, and in all but authorship has been got up with such disregard of expense, that it is a pity "Samuel Brothers," of 29 Ludgate-hill, and of "Sydenham Trousers" notoriety, did not take the pains to have it edited with some little show of care. A little money spent in that manner would have helped to make it more valuable in its way than it can possibly prove in its present form. This Historical Sketch is to be followed by other volumes on "The Natural History of Wool," and on "The Mechanical History of Woollen Manufacture." We hope these will be edited by some one who knows when he has written intelligible English and when he has not—which is more than the editor of the volume before us knows. It consists, nevertheless, of an historical narrative, the reading of which would add much to the knowledge of many.

MAJOR RHODES' TENTS.

THE board of medical officers appointed by the Duke of Cambridge to report on the hospital tent which has been invented by Major Rhodes—one of which has been for some time in use in the grounds attached to the garrison hospital at Chatham—having made a very favourable report of the invention, the Commander-in-Chief gave directions for another description of Major Rhodes' tent, called the "Field hospital tent," to be pitched there. Major Rhodes accordingly arrived at Chatham on Saturday afternoon last, for the purpose of superintending the erection of this field tent, which, like the others invented by him, is of simple construction. "The ground having been accordingly selected, the tent was pitched," says the *Times*' correspondent, "by four men in a comparatively short space of time, notwithstanding that three of the men who assisted knew nothing whatever of tents, and had probably never seen a military tent pitched in their lives. In this, as in his other tents, Major Rhodes entirely discards the use of the clumsy and inconvenient tent-pole, the coverings being supported on pliable ribs of ashwood, the bottoms of which are fixed into the ground, the tops meeting in a wooden head, which also answers the purpose of a ventilator. The tent erected on Saturday is 20 feet in diameter, and affords ample accommodation for 20 patients, giving each patient a space of 3 feet by 7 feet, leaving a clear central space of

* The results obtained with the shells, noticed at page 9, (the centre of gravity being, in their case, in a forward position), were comparatively greater when the elevation was as much as 10°, than those obtained with Armstrong's. And they would have been still greater if I could have had at my disposal (which was far from being the case,) the superior mechanical means possessed by Sir W. Armstrong or Mr. Whitworth, for properly carrying the principle into practice. These are the first, and I believe the only projectiles of a proper length which have yet been successfully fired from a rifled cannon which does not load at the breech; and are, therefore, probably, with the exception of Sir W. Armstrong's, the only projectiles with which the effect I have been remarking upon could have been observed. From the high velocity maintained by these projectiles (about 1,000 feet a second), it appears probable that too high a value has hitherto been assigned to the resistance of the air, the terminal velocity of these projectiles (according to the ordinary computation) not much exceeding 700 feet a second."

6 feet diameter for the use of the medical officers and hospital attendants—an advantage which is, of course, out of the question in the present tents, where the pole monopolises the most important part of the interior. But perhaps the most valuable improvement in this tent is the excellent system of ventilation adopted."

Our Weekly Gossip.

WITH respect to the projected coinage of bronze, the thought has arisen in our mind as to whether Britannia as a design for the reverse of them ought not to be sacrificed. For nearly 200 years has that very tall lady been doing duty as a device for the reverse of the copper coinage of these realms, and the question comes whether it is not now time to relieve guard, and dismiss Britannia, her shield and her trident, to the limbo of bygone things. The origin of the design was questionable enough, and it is not needful for us to perpetuate the memory of Charles II., or any of his beauties, one of whom sat for the original Britannia. Britannia, in the literal sense, would doubtless remain ruler of the sea, though her tall representative disappeared for ever from the coinage of the realm. At any rate she does not rule the wave the more safely because that person has sat so long in her helmet looking wistfully out at—nothing. The omission of Britannia and the ledge of rock upon which she, with all her stage properties, is so calmly resting, would make room for a totally new device for the neater pieces of money with which we are shortly to be favoured, and would furnish a field for the trial of skill invited in another column among engravers.

The Science and Art Department of the Committee of Council on Education, have issued the following circular:—"Teachers wishing to attend the examinations of science and art department in—1 practical and descriptive geometry, with mechanical and machine drawing, and building construction: 2, physics; 3, chemistry; 4, geology and mineralogy (applied to mining); 5, natural history,—for the purpose of obtaining augmentation grants to their salaries (under the science minute of the 2nd June, 1859), must send their names, addresses, and present occupation, to the secretary of the department, South Kensington, on or before the 31st October, 1859. The examinations will be held in the Metropolis in the last week of November. Certificates of three (grades will be granted in each subject, giving the holder an augmentation grant of 10*l.*, 15*l.*, or 20*l.* a year on each certificate while giving instruction to a class of operatives in that subject. These payments will be in addition to the value of any certificates of competency for giving primary instruction, should the teacher have already obtained any such from the Committee of Council on Education."

The Atlantic Telegraph Company publish the following letter from Sir Charles Yorke, Military Secretary to the Commander-in-Chief:—"Horse Guards, Aug. 8, Sir,—With reference to my letter of the 8th ult., in answer to your inquiry as to any messages having ever been transmitted to Newfoundland by the Atlantic Telegraph during the time it was in operation last year, I am directed by the General Commanding-in-Chief to acquaint you that replies have been received from the general officers commanding the troops in Canada and Nova Scotia to the effect that a telegram dated London, England, August 31, 1858, respecting the 39th Regiment, was received at Montreal on the 3rd September and answered on the following day, and that a telegram of the same date respecting the 62nd Regiment was received at Halifax on the day of its transmission—namely, the 31st of August, 1858. I have the honour to be, Sir, your Obedient servant, C. YORKE. A. T. Hamilton, Esq., Director of the Atlantic Telegraph Company."

The following may serve a useful purpose, although we cannot ourselves share all the sentiments of the writer:—"Gentlemen,—Having had the pleasure of seeing Mr. Clifford's boat-lowering apparatus long before it had obtained popularity, I have watched it with interest ever since, and can bear testimony to some of the uphill work of the inventor. Mr. C. has briefly and mildly answered the shabby allusion of "Nauticus" to "a person of an opposite calling." The narrow-minded feeling from which it emanates, is unfortunately so prevalent that a protest should be occasionally made against it. A father hears of an opening which he thinks will suit his son, and, with the very best intentions on his part, places his son in a situation for which he is totally unfit. It soon appears that the son has talents which cannot possibly be made use of in his calling; he is, in fact, "of an

opposite calling to what he ought to be," a "square man in a round hole," and whenever he attempts to obtain employment in a sphere in which his talents may be used, the answer is, "Oh, you are of an opposite calling." Now, "Nauticus" maintains by the above sentence that this square man ought not to be in a square hole. The majority of our great men aptly illustrate the subject, and what "Nauticus" would call the rule is clearly the exception—the fact being that our most successful inventors have been "persons of an opposite calling." A man is brought up as a herb-seller who is a profound mathematician. A boy is sent to mind a booksellers' shop, who is destined to become a great chemist; a miner becomes an eminent engineer; a mathematical instrument maker becomes the greatest improver of the steam-engine; and even "Nauticus" has ventured into subjects that his father never dreamed of. I do hope, therefore, that I shall never see such a remark again in the *Mechanics' Magazine*, although every advertisement states the necessity for a certificate of "previous occupation in the same line," no one being deemed capable of sucking eggs without a certificate from his grandmother! I am, gentlemen, your obedient servant, T. MOY. 1 Clifford's Inn, Aug. 13, 1859.

"Another discovery which occupies the Emperor for the moment to the exclusion of all other discoveries of the same nature," says the Paris correspondent of the *Morning Star*, "is a new machine for the arming of ships of war, which is said to be the most terrible engine of destruction yet invented. This machine consists in a combination of a whole broadside, being constructed so as to be fired at once, and to be directed to any given point, so that no enemy's ship, however powerful, could resist the shock, which would sink a whole fleet if within range. The contrivance is said to be an improvement on the infernal machine of Fieschi, which you must remember was a radius of small guns. So that you see even treason has its uses, and if the Fieschi artillery be but charged with the Orsini shell, why then destruction of human life will be achieved upon the grandest scale! The machine, which as yet bears no name, is to be acted upon by electricity, as no gunner could withstand the recoil (?). As the reporter of the superb invention naively exclaims, 'Here is an invention which will leave far behind it the famous Armstrong gun, just tested with so much success in England.'"

Mr. Ward's newly invented arrangement of flag-signals, submitted for the approval of the Lords of the Admiralty, was tested at Woolwich this week, on board the Commodore's flagship *Fisgard*. The following account of the invention was written by the *Times* correspondent: "The flags are half-a-yard wide and three yards long, in pendant fashion, and, according to the code of instructions for corresponding from ship to ship at sea, the blue flag was run up to the maintop, as a preparatory pendant, announcing the desire to communicate, and is also hoisted between each word so as to divide them into sentences. The coloured flag appeared at the mizen and foretop masts, forming the message, which was clearly distinguished and understood at the given distance. In a dead calm, when the flags cannot float, a line is run across from the mainmast head to the mizen mast head, or from one yardarm to another, so that the flags may hang down and be visible, as in a breeze. Commodore the Hon. J. R. Drummond, for whose inspection the trials of the new flags and also the ocean marine telegraph, by the same inventor, have been performed at Woolwich, has ordered the construction of full sized instruments of the last-named invention, which will shortly be tested at Woolwich, preparatory to a trial at sea and on the coast."

It is stated that the design of the rifled cannon used by the French was offered to the British Government in 1855. A similar invention by Count Cavalli, of the Piedmontese service, was also offered to our Government, but his plans were referred backwards and forwards until they were lost sight of.

NOTICES.

The *Mechanics' Magazine* will be sent free by post to all subscribers of £1 *ls.* 8*d.*, annually, payable in advance. Post Office Orders to be made payable to R. A. Brooman, at the Post Office, Fleet Street, London, E.C.

TO ADVERTISERS.

All advertisements occupying less than half-a-column are charged at the rate of 5*d.* per line for any number; insertions less than 13; for 13 insertions, 4*d.* per line; and for 52 insertions, 3*d.* per line.

Each line consists of 10 words, the first line counting as two. Wood-cuts are charged at the same rate as type for the space occupied.

Special Arrangements for larger or Serial Advertisements. To ensure insertion, Advertisements must reach the Office by 5 o'clock on Thursday evening each week. None can be received after that time for the ensuing number.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgement:—

STEAM ENGINES, &c., 2906, 7, 9.
BOILERS AND THEIR FURNACES, &c. *None.*
ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 2981, 2984, 2985, 3004, 6, 12, 20, 22, 36.
SHIPS AND BOATS, including their fittings, 2982, 22.
CULTIVATION OF THE SOIL, including agricultural and horticultural implements and machines, 2977, 2980, 2986, 16, 39.
FOOD AND BEVERAGES, including apparatus for preparing food for men and animals, 21.
FIBROUS FABRICS, including machinery for treating flax, pulp, paper, &c., 2979, 2991, 10, 13, 25, 27, 29, 33, 37, 38, 40, 44, 46, 47, 49, 52, 53, 54, 59.
BUILDINGS AND BUILDING MATERIALS, including sewers, drain-pipes, brick and tile machines, &c., 19, 45.
LIGHTING, HEATING, AND VENTILATING, 2967, 5, 24, 35, 35.
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 298, 2, 4, 43, 57.
METALS, including apparatus for their manufacture, 306, 40.
CHEMISTRY AND PHOTOGRAPHY, 2983, 58.
ELECTRICAL APPARATUS, 2984, 2997, 31, 51, 56.
WARFARE, 2990.
LETTER PRESS PRINTING &c. *None.*
MISCELLANEOUS, 2978, 2985, 2988, 2999, 2992, 2994, 2991, 2995, 3000, 3002, 3003, 3005, 3006, 1, 3, 8, 11, 14, 15, 17, 18, 28, 30, 32, 34, 42, 48, 50.

2978. H. HUTCHINSON. "Improvements in the manufacture of india-rubber goods." Dated Dec. 29, 1858.

Here in coating sheets of cloth, leather, or other material with india-rubber, when such sheets are to be cut up into shaped pieces, the patentee only coats such sheets with india-rubber at certain places, in pieces of the size and form required, and this he does by passing the sheets of cloth, &c., together with a sheet of india-rubber prepared in the usual manner, between rollers, on one of which a raised pattern is fixed, and this raised pattern, by pressing the sheet of cloth, &c., and the india-rubber together, causes the india-rubber to combine with the sheet of cloth, &c., at the parts touched by the pattern, whilst at the parts which receive no pressure no adhesion is produced between the cloth and the india-rubber. *Patent completed.*

2979. S. MORAND. "Improvements in apparatus for stretching fabrics." Dated Dec. 29, 1858.

This consists in forming a series of blocks which are to move in suitable grooves, simply touching each other at their ends, without being linked or attached together, but in place of making the blocks with square or flat ends, so that when in a straight line the whole of the surfaces of the two ends of two neighbouring blocks shall be in contact, the inventor so forms the ends of each block that when a series of them are in a straight line the neighbouring ones shall only touch each other at a point. Each end of each block is made to incline from the centre outwards to the four angles, by which when a number are set in a straight line the neighbouring ones will admit of passing in curved and inclined lines. Each block is made with a groove through which pins pass to admit of the endless rows of blocks being moved by toothed or chain wheels. *Patent abandoned.*

2980. A. V. NEWTON. Improvements in machinery for reaping and mowing." (A communication.) Dated Dec. 29, 1858.

This consists, 1, in connecting the finger bar to the main frame by an intermediate frame, the said intermediate frame being hinged to the main frame (front and rear) in a line, or nearly so, with the crank-shaft. 2, in a peculiar mode of raising and lowering the main frame so as to adapt the machine to mowing and reaping. 3, in the mounting of the cutter-bar in rear of the front edge of, and over the finger bar, so as to allow the cutting edge of the cutters to cross the edge of the finger-bar, and clip the grass, &c., as near as possible to the finger-bar. 4, in a method of construction of the finger-bars and guard-fingers, and the manner of securing the guard-fingers to the finger-bar, and of operating the cutters therein. *Patent completed.*

2981. T. W. GOWING. "An improved roughing for the shoes of horses and other like animals." Dated Dec. 29, 1858.

Here the roughing consists of nails formed with spikes or projecting surfaces, and with shoulders which bear upon the outside or bottom of the shoe itself. *Patent abandoned.*

2982. H. N. MAYNARD. "Improvements in anchors, and in the manufacture of anchors." Dated Dec. 30, 1858.

This consists in making anchors of plates, bars, angle, and other sections of iron, cut to the necessary shapes, and rivetted, bolted, or welded together so as to obtain greater facility in their manufacture, and the advantage of an increase of strength throughout, with the use of much less weight of metal. *Patent abandoned.*

2983. F. PULS. "The treatment of hydrocarbons." Dated Dec. 30, 1858.

The inventor oxidizes hydrocarbons by acids or otherwise, and uses them in this oxidized state, either alone or mixed with other fatty substances, for combining them with alkaline lies, which combinations he uses as a lubricating material. *Patent abandoned.*

2984. H. C. VION. "A new mode of obtaining atmospheric electricity, and terrestrial electricity, and industrial applications, and in apparatus for the same." Dated Dec. 30, 1858.

This consists in an electric pile formed by the earth and by the atmosphere. The earth is the negative pole. The atmosphere the positive pole. *Patent completed.*

2985. F. JOHNSON and J. H. G. WELLS. "Improvements in constructing breakwaters, and other similar structures." Dated Dec. 30, 1858.

This consists in presenting to the action of the waves a surface of timber or iron, or both combined, held in a grooved iron or wood framing fixed to piers constructed of iron or wood piles, with screw at foot of same, the piles being firmly braced together, and on the piers of which a superstructure may be erected for use as a pier, &c. *Patent abandoned.*

2986. J. F. C. HEYNE. "Improvements in railway chairs and rails, and in the mode of fixing the same." Dated Dec. 30, 1858.

This consists of shaping longitudinally the inner surface of the rails or metals so as to present a transverse curvilinear concavity to the back of the chair, which is also placed in similar manner for receiving the same, whilst the outer surface of the rail is provided with suitable key plates fitting closely within the ordinary channel or groove of the same, and the whole secured together through the medium of bolts and nuts, by which arrangement the rails or metals on being worn out and flattened at the upper face, or portion thereof, may be taken out and reversed with greater advantage than at present, a key-way and key being employed in connection with the seat of the chair for tightening the rail when required, together with a double surface chair and tightening bolts at the joints, or the junction of the rails. *Patent abandoned.*

2987. T. BELL. "Improvements in purifying gas." Dated Dec. 30, 1858.

The patentee employs the residuum from the working of Longmaid's process for the manufacture of sulphate of soda. *Patent completed.*

2988. R. A. BROOMAN. "Improvements in stoppering or closing bottles, jars, and other like vessels." (A communication.) Dated Dec. 30, 1858.

On the neck of the bottle, &c., to be closed two screw threads are cast of a diminishing pitch from the mouth downwards. Two indentations are made in opposite sides in a capsule of metal, and are so formed as to screw into or under the screw threads in the bottle, &c., and retain the capsule in the bottle; by simply turning the capsule in the reverse direction it will be unscrewed and released. The top of the capsule on the inside is finished with a block of cork, caoutchouc, &c. The bottle, &c., may be hermetically closed by screwing the capsule tightly down on the neck thereof. Where the screw threads on the bottle, &c., are of glass, the inventor roughens their under surfaces to prevent the indentations on the capsules accidentally slipping up them. *Patent abandoned.*

2989. R. A. BROOMAN. "Improvements in washing and drying machinery and apparatuses." (A communication.) Dated Dec. 30, 1858.

According to one modification of this invention, of which there are several included in the specification, the machines are made of beaters, or beaters and rollers, as follows:—Several stampers are suspended from a cranked axis, which upon being rotated, causes the stampers alternately to rise and fall upon the articles to be washed, which are held in a trough with perforated sides and bottom, the bottom being under water contained in an outer trough. Under the bottom are springs which have a tendency to force up the inner trough, and greatly assist the washing operation. Inclined sides may be fitted to the outer trough on which the articles washed may

be placed to drain, and they may be also passed between rollers to express the water after being removed from the trough. *Patent completed.*

2990. R. A. BROOMAN. "Improvements in revolving fire-arms." (A communication.) Dated December 30, 1858.

This consists in so forming and fitting the revolving breech-piece of revolving fire-arms that when they have to be charged it may be turned either downward, or to one side, or otherwise about a hinge or joint, either in conjunction with, or separate from, the barrel, and in fixing the said breech-piece in place after the chambers have been charged, by a rod passing through the breech-piece and engaging at the rear end in a female screw-thread, or other holding part, by a male screw thread, or a gaining or other projection. When a male screw-thread is used it is formed on a part of the circumference of the rod only, and makes about one-fourth a revolution. In order to withdraw the cartridges from the breech-chambers, the patentee sometimes makes use of a rod which is carried in the butt of the stock of the arm; or he employs a rod with a washer or ring at the extremity so arranged as to force all the cartridges out at once. *Patent completed.*

2991. R. A. BROOMAN. "Improvements in machines for embroidering." (A communication.) Dated Dec. 30, 1858.

According to this invention the festoon stitch is the result of two threads introduced into the fabric to be ornamented by one needle and one hook. The needle placed under the fabric is slightly bent back in order to allow the hook taking the thread from this needle to form a loop; the hook placed above the fabric directs the second thread in such manner as to form a knot above the fabric. Over the fabric is a small instrument called a pusher (*poussette*) intended to prepare the loop formed by the hook in order that the needle in again rising may not fail to seize the thread. Under the fabric is another instrument called a thread-grip (*serre-fil*) intended to tighten the knot formed above the fabric every time the hook recedes, and previous to the descent of the needle. *Patent completed.*

2992. R. A. BROOMAN. "Improvements in machinery for splitting or dividing hides, skins, leather, and other like materials." (A communication.) Dated December 30, 1858.

This consists 1, in the use of knives or cutters by preference serrated, and attached to a cutter-carrier the height of which is regulated by screws connected with its supports, and which receives a reciprocating motion from a main shaft by a connecting rod, or otherwise. 2, in the use of a roller for supporting the hides, skins, &c., as they are cut, which roller is incapable of ascending or descending motions, being supported in fixed bearings. 3, in the use of a moveable bar or presser-carrier for carrying a number of pressers which bear on the hides, skins, &c., as they are cut immediately in front of the knives, and which are kept down upon the hides, skins, &c., by springs. 4, in forming the said pressers each square or rectangular in section at their lower parts, and sinking these parts in a groove in the carrier to prevent their turning round, or otherwise moving improperly. 5, in giving motion to the cutter-carrier by a connecting rod or other appliance at the end of the said carrier, and not at or near the middle, to prevent trembling or unsteadiness of action. 6, in an arrangement of anti-frictional or other supports to enable the cutter-carrier to slide smoothly in its bearings. 7, in the use of a roller of less diameter at the middle than at the ends, for winding up the cut hides, skins, &c., and the method of driving this roller by means of worms and endless screws. 8, in a method of throwing the said roller in and out of gear by suitable levers, handles, &c. *Patent completed.*

2993. R. A. BROOMAN. "An improvement in pipes for smoking." (A communication.) Dated Dec. 30, 1858.

The object here is to prevent the essential oil of the tobacco and nicotine from being drawn into the mouth of the smoker. The invention consists in fitting a chamber between the bowl and the mouth-piece, and in placing tobacco, sponge, &c., therein to absorb the essential oil; also a piece of perforated plate, wire gauze, net, or other suitable fabric between the tobacco in the chamber and the mouth-piece. *Patent abandoned.*

2994. W. BURGESS. "Improvements in apparatuses for converting reciprocating into rotary motion." (A communication.) Dated December 30, 1858.

This consists, 1, in the use of a sliding clamp block on a sliding rod in combination with an alternating clamping lever worked by a reciprocating rod, so that each alternation of the reciprocating rod the clampers of the clamping lever take hold of the opposite sides of an endless belt to continue its motion,

and thus impart rotary motion to a shaft or shafts, over which the belt is passed. 2, in the addition to a treadle to drive the reciprocating rod of an elastic roasting spring to the underside of the foot rest of the treadle, so that when the toe of the foot rest is depressed, and in the giving back of the pressure of the foot the spring will cause the rest to follow the foot up. *Patent completed.*

2995. S. S. BATESON. "Improvements in generating steam." Dated Dec. 30, 1858.

This consists in causing a supply of water to be forced by any suitable feed or force pump through a coiled pipe placed inside the body of the furnace fire and opening into the boiler. *Patent completed.*

2996. J. KNOWLEDEN and R. D. EDWARDS. "Improvements in hydraulic engines and apparatus connected therewith." Dated Dec. 30, 1858.

The patentee constructs the engine or apparatus with one or more cylinders with piston or ramrods, valves, &c., to be actuated by water pressure from the mains of the streets, or other sources; and when considered they arrange with the apparatus an air chamber, for the purpose of arresting, checking, or softening by means of a volume of compressed air any violent action produced by the sudden stoppage of water, or by the weights to be stayed. The invention is applicable to various purposes. *Patent completed.*

2997. J. W. DUNCAN. "Improvements in or connected with appliances for transmitting or conducting signals or action by electricity or magnetism, and in the method of testing insulating materials, combinations, or structures, for conducting electricity, and in treating malconstructed or invalid electric telegraph cables, and in utilizing parts of certain cables, or the application otherwise of such structures, and in certain insulating compounds, and in the apparatus and machinery used in connection therewith." Dated Dec. 30, 1858.

The specification of this invention is so excessively elaborate that we cannot afford space for an intelligible abstract of it. *Patent completed.*

2998. J. H. JOHNSON. "Improvements in the permanent way of railways." (A communication.) Dated Dec. 31, 1858.

This consists in the use of fish-plates, or bars which hold the rails at their base, and by their lower rib or flange, in place of holding them on the sides of the web or narrow portion thereof. These fishes, which may be termed "under fishes," make use of the lower part of the rails for the purpose of consolidating their union, and are shaped to suit the various forms of rails to which they may be applied. There are modifications included. *Patent completed.*

2999. J. H. JOHNSON. "Improvements in the manufacture or production of boots and shoes, or other coverings for the feet, and in the machinery and apparatus employed in such manufacture." (A communication.) Dated Dec. 31, 1858.

This consists, 1, in an improved last or stand upon which the bottoms of boots or shoes are united to the uppers. 2, in countersinking the holes in which the fastenings are inserted for uniting the soles and heels to each other, and to the uppers or fronts. 3, in a method of uniting the soles and heels to the other parts, and in a machine for that purpose. 4, in regulating the length of each fastening used in uniting the soles and heels with the uppers by a cam, on the surface of which the end of a lever rests, and which lever feeds the material into dies or shapers. *Patent completed.*

3000. H. ROBIN. "Improvements in reaping machines." Dated Dec. 31, 1858.

Here the cutting and gleanings machinery is supported by a framework, which allows the resisting and motive power to have direct play. It is fixed upon the axle-tree of the wheels, and fastened to the pole, which is lengthened behind, and the axis of which corresponds to the centre of the reaping machine. A horizontal cross-bar is fixed against the pole on each side to the collar of the horses. The varying height of the cross-bar allows a greater or lesser inclination of the framework, and consequently the wheat, hay, or grain may be reaped at any given altitude. *Patent completed.*

3001. M. D. WYATT. "Improvements in tiles and tesserae and other wall coverings, and in the means of securing the same to walls and buildings." Dated Dec. 31, 1858.

The patentee makes the tile with a projecting piece of a dovetail form at the upper part, which piece may project about $3\frac{1}{4}$ or 4 inches, or a little more than the height of the thickest course of ordinary brickwork. Thus, at whatever part of the wall the tile may be applied, the dovetail piece will cross a course of the mortar. Between the bricks a nail is driven into the mortar on each side of the dovetail, and the tile is thus secured. The next tile is made to lap over and hide the dovetail, which is set back in a different plane

from the face of the tile. There are modifications included. *Patent completed.*

3002. T. Z. L. MAUREL. "An apparatus projecting indefinitely the working of any mechanism set in motion by springs, more generally applicable to clock-making." Dated Dec. 31, 1858.

The inventor proposes to furnish any mechanism moved by springs—a clock, for instance—with a series of small barrels of equal size, turning in the ordinary manner, independent of their axes, and communicating with each other by wheels of equal diameter. Each of these barrels has a spring attached by one extremity to the drum or cylinder of its barrel, and by the other to its spindle, the position of each spring being regulated by the number of barrels employed. The shaft of the first of these barrels carries at one extremity a handle by which it is turned, and at the other a pawl and pinion to prevent its return; the shaft of the last barrel carries a wheel, by which it is connected by the ordinary clockwork. Supposing twelve barrels to be used, by turning the handle on the shaft of barrel No. 1, he successively winds up the springs of each barrel up to No. 12 (he usually places two barrels upon each shaft, excepting the first and last, which carry but one), the shaft of which carries the wheel, gearing on to the ordinary clockwork. The clock being set in motion, it follows that as the spring No. 12 goes down, it is every moment wound up by spring No. 11, and so throughout the series, until all the springs run down together. *Patent abandoned.*

3003. J. LESS and W. HEAP. "Improvements in machinery for punching square holes in the ends of rollers and other articles." Dated Dec. 31, 1858.

This consists in so constructing machinery for punching square holes in the ends of rollers and other articles, that each article is presented in succession to a series of punches fitted in a circular bush, to which an up and down or to and fro motion is given. *Patent completed.*

3004. J. H. SIEVERS. "Apparatus for tightening and releasing the belly-bands of riding saddles." (A communication.) Dated Dec. 31, 1858.

The object here is to enable the rider while on horseback to tighten the belly-bands should it be required, and to facilitate the putting on and taking off of saddles. The apparatus is contained in a flat box of metal fixed to the right-hand side of the saddle. *Patent abandoned.*

3005. F. W. A. CASPER and G. H. SCHMAHL. "Using spart or Spanish broom in manufacturing seats of all descriptions." Dated Dec. 31, 1858.

This consists in using spart, a kind of tender shrub growing in some mountainous parts of Spain, for manufacturing seats of all descriptions, but especially those for the use of kiosques, bowers, green arbours, &c. *Patent completed.*

3006. L. A. NORMANDY. "A new system of shaft tugs." (A communication.) Dated Dec. 31, 1858.

This is essentially composed of metal supports, coated or not with paint, &c. These supports are attached by buckles or otherwise to the harness. *Patent completed.*

3007. J. H. JOHNSON. "Improvements in the manufacture or production and casting of steel, and in the apparatus employed therein." (A communication.) Dated Dec. 31, 1858.

This relates to certain processes for manufacturing and melting steel, whereby cast steel may be obtained in sufficient abundance for casting articles of extreme size, such as ordnance or large bells, &c. By this invention, also, the use of the ordinary melting pots is dispensed with. *Patent completed.*

1. J. T. PITMAN. "An improved mode of making and fitting bungs to casks and other vessels." (A communication.) Dated Jan. 1, 1859.

This consists in forming a screw on the bung or stopple, and a corresponding one at the hole in the stave of the barrel or cask by burning. The invention is not fully described apart from the drawings. *Patent completed.*

2. H. C. TRAPHAGEN. "Improvements in skirts for ladies." Dated Jan. 1, 1859.

This consists in attaching to the body of a skirt a series of light air-tight tubes, to be inflated with air. *Patent abandoned.*

3. A. ANDERSON. "An improvement in governors for machinery." Dated Jan. 1, 1859.

This invention is an application of the sensitiveness of the well-known instrument called the gyroscope to the regulation of the speed of machinery. *Patent abandoned.*

4. B. J. GOSTRAV. "An improved gridiron, which may form a complete cooking apparatus." Dated Jan. 1, 1859.

This consists in a cooking apparatus in which the fuel is placed upon a shelf formed of wire gauze, the

meat, &c., to be cooked being placed immediately underneath. *Patent completed.*

5. J. E. DROUOT. "Improvements in bakers' ovens." Dated Jan. 1, 1859.

This consists in a mode of constructing bakers' ovens so that the patentee can bake, and produce at the same time the steam necessary for working a motive power. *Patent completed.*

6. W. FOOTMAN. "Improvements in brakes for retarding and stopping railway trains, carriages, and other vehicles." Dated Jan. 1, 1859.

Here a solid or tubular shaft is placed in bearings beneath the carriage. On this longitudinal shaft is formed or fixed a short endless worm or screw gearing with a toothed wheel fixed on a transverse or brake shaft, and near each end or in the middle of this brake shaft are formed two cranks or excentrics, to which the rods of the brake blocks are attached. When the longitudinal shaft is made to revolve, its endless screw turns the toothed wheel fixed on the brake shaft, and causes the cranks or excentrics to act and give a thrust to each of the rods to which the brake blocks are attached, so as to press the blocks against the peripheries of the wheels of the carriages to which the brakes are applied. There are modifications included. *Patent abandoned.*

7. J. OLIVER. "Improvements in lubricators for steam engine cylinders." Dated Jan. 1, 1859.

Here the oil, &c., is placed in a vessel which communicates with the interior of the steam engine cylinder by a neck or pipe, and is covered by a screw cap. In this neck or pipe is a small chamber containing a valve which rests upon a seat at the bottom of the chamber. The upper surface of this valve is also faced; or two valves are connected together, and the upper face or valve shuts against an inverted seat in the top of the chamber. Thus the valve is closed against the lower seat when down, and against the upper seat when up. The valve may be guided by a triangular stem or otherwise. *Patent completed.*

8. J. WALKLAND. "An apparatus for lighting cigars and tobacco." Dated Jan. 1, 1859.

This relates to a portable metallic box or case adapted for the use of smokers; it is formed with indentations for the reception of any desired number of small wafers of suitable material, steeped in a solution of nitre, or other salt that will render them combustible without causing them to be explosive or susceptible of bursting into flame. In the centre of each wafer is a hole bushed with a detonating compound, and in the centre of the receiver or indentation in the case is a corresponding hole, and through these holes a small rod or needle is drawn to produce ignition by friction. *Patent abandoned.*

9. J. GARFORTH. "Certain improvements in steam engines." Dated Jan. 1, 1859.

This relates to reducing the area or steam surface, of the cylinder and piston so as to enable the inventor to employ high pressure steam in the cylinders (as it comes from the boiler or nearly so) during the entire length of the stroke (if required). The invention consists in the use of two cylinders, one arranged within the other, the inner cylinder being supplied with steam at a low pressure, and the space between the cylinders being supplied with high or low pressure steam, the piston of the outer cylinder being annular in form, and having two piston-rods which are connected by a crosshead to the rod of the centre piston. *Patent abandoned.*

10. H. ASHWORTH. "Certain improvements in power looms for weaving." Dated Jan. 1, 1859.

This consists in providing a roll of flannel, &c., within the picker so that the motion of the picker along the wire or guide shall effect the lubrication, by carrying with it the flannel roll which is to contain the oil of lubrication, and which may be supplied thereto through a hole in the top of the picker. *Patent abandoned.*

11. R. SMITH. "Improvements in casting, applicable to printing surfaces, and for other purposes." Dated Jan. 1, 1859.

This relates to arrangements applicable in casting various articles, and designed in part to facilitate the withdrawal of the casting from the mould, and in part to facilitate the removal of superfluous metal. The details of the invention may be variously modified. *Patent abandoned.*

12. P. E. GUERINOT. "Improvements in the application of an apparatus to railway locomotives, waggons, and carriages, for the purpose of lessening the effect of concussion in the event of collision." Dated Jan. 1, 1859.

This relates to a previous patent, and the chief feature in the invention is the use of pointed steel rods and corresponding lead blocks, the steel rods being forced into the lead blocks in the event of collision. *Patent completed.*

13. W. ECCLES. "Improving the machinery or

apparatus for regulating the tension of the twist threads or warp whilst it is weaving in power looms into cloth." Dated Jan. 1, 1859.

This relates, 1, to certain improvements in the "back beater," otherwise "back rest;" and, 2, to the weight levers or apparatus, which, acting on the ropes at the back of the loom, keep the yarn in a state of tension. *Patent completed.*

14. M. WIGZELL. "An improved form of nail or driving article." Dated Jan. 1, 1859.

The forms of nails described are wholly or partly twisted or spiral, and are such that nails made as described offer a greater resistance to drawing than the ordinary nails or other driving articles, as they cannot when driven be withdrawn by a direct strain, without tearing away the wood into which they are driven. *Patent completed.*

15. A. PRINCE. "Improvements in the construction of cylindrical presses." (A communication.) Dated Jan. 1, 1859.

This consists of certain mechanical arrangements whereby a continuous pressure is obtained, and is particularly adapted to the extraction of juice from fruit or plants, oils, and other liquid matters. *Patent abandoned.*

16. W. A. VON KANIG. "Improvements in machinery or apparatus for digging and cultivating land." Dated Jan. 1, 1859.

This relates to arrangements whereby mechanical diggers or workers are contrived for digging up, working, and cultivating land under various circumstances, under the operative power of steam, or other available mover. *Patent completed.*

17. J. HARRIS. "Improvements in apparatuses for regulating the pressure and flow of steam, water, and other fluids." Dated Jan. 1, 1859.

This relates principally to apparatuses for reducing high pressure fluids to any given pressure below that in the boiler, water main, gas main, or any other main, or for allowing steam or other fluid when it has attained a given pressure to escape either into a second receiver, or into the open air through a safety valve or danger signal or otherwise. The various features comprised in this invention we shall probably describe in a future number. *Patent completed.*

18. J. WOOD. "Improvements in cutting and finishing corks, and in machinery used for such purposes." (A communication.) Dated Jan. 1, 1859.

This consists in the use of an adjustable table, over which a series of spindles, furnished at their lower ends with sharp-pointed cutters, are so mounted as to be capable of rising and falling at regular intervals by means of cams, and at each descent each of the spindles cuts a cork from the block of cork wood placed beneath them. These spindles are driven by bands from a drum. There are various other details, but the invention is not fully described apart from the drawings. *Patent completed.*

19. G. SKINNER and J. WHALLEY. "Improvements in the manufacture of ornamental and other tiles and other similar articles." Dated Jan. 1, 1859.

The patentees use the materials in a semi-fluid state, and employ a metal case in two parts, the sides of which are lined with filtering material, and when used are firmly bolted together so as to constitute a species of filter. This instrument they call a power loom, and in it tiles, &c., are formed and decorated at the same time. *Patent completed.*

20. J. BROWN, jun. "Improvements in buffers, draw springs, and bearing springs." Dated Jan. 1, 1859.

This consists in constructing railway buffers, draw springs, or bearing springs each with two or more spiral springs, supported and kept in their proper positions by tubes connected together by telescopic joints, each spring having a separate set of tubes. *Patent abandoned.*

21. G. T. BOUSFIELD. "Improvements in machinery for forming dough into cakes or bread crackers." (A communication.) Dated Jan. 1, 1859.

This invention is not described apart from the drawings. *Patent completed.*

22. A. L. LEVEQUE. "An improved apparatus for subduing or stopping runaway or restive horses." Dated Jan. 1, 1859.

This consists in providing the headstall or other parts of horses' bridles with an apparatus to be actuated by the driver or horseman, and by means of which suitable parts of the horses' sight may be covered for inducing the horse to put his head in the required position for the due acting of the bit. *Patent completed.*

23. J. B. MORGAN. "Improvements in propelling navigable vessels." Dated Jan. 1, 1859.

This consists of a submerged vertical flat blade or vane, of a square form, mounted vertically between the two outer ends of two horizontal arms so that it is at liberty to turn freely on its axis from about 45° to 80°. The arms have a horizontal semi-circular

action communicated to them through a vertical riving shaft to which one or both of the arms are taken. The motive power is applied to the vertical riving shaft by a rack and pinion, crank, &c. The ropelling blade is placed in an opening in the dead wood of the run of the vessel, or in a frame work placed beyond the stern, or projecting forward from the bow, or placed below the keel. *Patent completed.*

24. J. LUIS. "New economical candles." (A communication.) Dated Jan. 3, 1859.

These candles are of two sets, one having two wicks lasting from 5 to 6½ hours, and giving a light equal to two and one third candles; the other has but a single plaited wick not occupying the centre of the grease. *Patent completed.*

25. R. TEMPEST and J. TOMLINSON. "Improvements in certain machines for preparing cotton and other fibrous materials." Dated Jan. 3, 1859.

Here the catch lever to which the spout or trumpet mouth is fixed is jointed between its fulcrum and the calender rollers, so that when the sliver breaks the lever with the spout or trumpet mouth can easily be raised to facilitate the removal of the knot or other impurity which caused the sliver to break. There is also an opening spout, instead of a circular trumpet mouth to guide the sliver to the calender rollers. *Patent completed.*

26. M. A. F. MENNONS. "Certain improvements in steam generators." (A communication) Dated Jan. 3, 1859.

This consists in the addition to boilers and other steam recipients of an auxiliary feeding apparatus for the introduction of cleansing or protecting solutions, and in the arrangement for effecting this introduction during the work of the boiler by the pressure of the steam evolved. *Patent completed.*

27. C. B. BLYTH. "Improvements in machinery for preparing and treating jute, hemp, flax, and other fibrous materials." Dated January 3, 1859.

This relates to machinery employed in the operation of "softening." It consists in arranging machinery with three or more rows of rollers, which the patentee mounts within the same machine framing, and drives by bevil gearing. He feeds the material between two rows of rollers—say the bottom and middle set of rollers, when three rollers or sets of rollers are used—and returns it back again between the middle and top row or set of rollers, by a return feeder, which carries the material from between the first set or rows up to between the next set or rows of rollers in the series composing the machine, when it is again subjected to a continuation of the treatment it received in its progress through the first set of rollers. *Patent completed.*

28. E. BALCHIN. "An improved construction of projectile, applicable to the whale fishery." Dated Jan. 3, 1859.

The patentee proposes to employ, in conjunction with the ordinary harpoon, a hollow lance or pointed shell, which is to contain a charge of powder, and may be fired into the whale with the view of striking some vital part while, or just before, the harpoon to which a line is attached is discharged as heretofore to secure the fish. *Patent completed.*

29. W. and T. RENTON and W. BINNS. "Improvements in raising the nap or pile of textile fabrics." Dated Jan. 3, 1859.

Here two raising cylinders are used and two beds. The fabric is kept distended, and is moved slowly over a bed in the shape of a trough, the fabric when being raised resting on the two sides of the trough, whilst the part of the fabric which is across the trough is allowed to assume a curved form, corresponding with the curvature of the raising cylinder, or the trough is filled with elastic material so as to present an elastic bed for the fabric. The first raising cylinder is wound round with fillet cards in a direction from the centre or middle outwards towards each end of the cylinder, so that in its revolution this cylinder will raise the nap on the fabric in a direction from the middle outwards towards the two selvages. The second raising cylinder sets the nap in the usual manner. *Patent completed.*

30. J. and T. FURNIVAL, J. DERRYSHIRE, and F. J. EMBRY. "Improvements in apparatus for supporting articles of china and earthenware in kilns and ovens." Dated Jan. 3, 1859.

This invention is not described apart from the drawings. *Patent completed.*

31. L. J. HIGHAM. "Improved means for obtaining submarine electrical conduction." Dated Jan. 4, 1859.

Here a jointed case is employed for protecting the insulated wire. *Patent abandoned.*

32. J. BUCHANAN. "Improvements in oil cans, or lubricating apparatus." Dated Jan. 4, 1859.

This oil can is intended to be used in lubricating the working parts of machinery. The oil reservoir is in

the form of a long narrow cone of tinned plate, the dropping discharge aperture being on the extreme end of the cone point. The base consists of a dished disc of tinned plate. This disc is concave externally, and through its centre there is entered a short and narrow slightly conical tube, open at both ends. This tube is soldered into the base disc, and when the can is upright it stands up to a little above the height at which it is intended that the oil should stand in the reservoir when newly supplied. The result of this arrangement is obvious. *Patent abandoned.*

33. J. B. JOYCE. "Improvement in means, machinery, or apparatus applicable to wool combing." Dated Jan. 4, 1859.

This relates to apparatus for drawing the wool from the combs of that class of combing machines wherein portable combs are used, and consists in so constructing and arranging machinery as to be self-acting for receiving the combs when taken from the combing machine, transferring them to the drawing-off rollers and nail strippers, and delivering them in a proper position for being replaced on the combing machine. *Patent completed.*

34. W. HOOD. "Improvements in racks and water cisterns for stables." Dated Jan. 4, 1859.

This invention was described and illustrated at page 76, No. 5 of the MECHANICS' MAGAZINE (New Series). *Patent completed.*

35. A. BEDBOROUGH. "An improved chimney cowl and ventilator." Dated Jan. 4, 1859.

This consists of an inner tube or conical-shaped flue, surrounded by an outer case, in the sides of which are transverse openings, with deflecting plates to give an upward direction to the air entering through them; about two to four inches more or less from the top of the central tube there is a stop plate which entirely covers all direct access to the tube from the top of the cowl. The smoke is carried off through apertures made and fitted in the form of an ornamented top which communicates with spaces outside of the covering plate before alluded to. Water is carried off from the covering plate through side apertures, and through tubes which direct the water through the transverse openings in the case outside of the inner tube and tend to keep them clean. *Patent completed.*

36. E. de FOREST. "An improvement in the manufacture of springs for carriages and other uses." (A communication.) Dated Jan. 4, 1859.

Here the vulcanized india-rubber, &c., is interposed between the weight to be supported and sustaining levers; or between the bearing surfaces and the sustaining levers. *Patent completed.*

37. F. CLARK. "Improvements in connecting knobs and handles to the spindles of locks and latches, and other articles of a like nature." Dated Jan. 5, 1859.

This invention is not described apart from the drawings. *Patent completed.*

38. W. DRAPER. "Improvements in machinery for printing on paper and other fabrics." Dated Jan. 5, 1859.

This consists in combining together two apparatuses, similar to those ordinarily used, so that two lengths of paper, &c., may be printed at the same time. It also consists in apparatus for moving the paper, &c., forward after each impression; also, in a method of applying the colour to colouring rollers. *Patent completed.*

39. J. HOWARD. "An improved construction of lever-neck plough." Dated Jan. 5, 1859.

This relates to ploughs which have a cast iron frame, and an adjustable lever for carrying the ploughshare, the chief object being to strengthen the socket end of the plough frame, and at the same time protect the lever neck from wear by keeping it from contact with the ground. It relates particularly to the plough patented July 3, 1853. The patentee now proposes to cast on the forward end of the plough-frame a socket, which is closed on all sides, but open at the ends to allow of the lever neck being passed through it. *Patent completed.*

40. R. RUMNEY and W. S. MACDONALD. "Improvements in printing and dyeing woven fabrics and yarns or threads." Dated Jan. 5, 1859.

This relates particularly to dyeing and printing fabrics and yarns or threads with colour derived from uric acid—murexide, for instance—and to combinations of other colouring matters therewith. *Patent completed.*

41. A. V. NEWTON. "An improvement in the process of, and improved apparatus for separating metals from their ores." (A communication.) Dated Jan. 5, 1859.

This relates to apparatus for effecting the intimate combination of gold or silver with mercury for separating the precious metals from the ground or pulverized ores of those metals. The apparatus (which is erected in a closed apartment heated by steam) con-

sists of a main shaft turning in bearings and carrying a series of chambers for receiving the ore. These chambers are arranged radially around the same hub or boss. Into these chambers the ore is placed, and and mercury added thereto. Rotary motion is given to the apparatus, and an artificial heat kept up. There are other features included in the invention. *Patent abandoned.*

42. W. CORFIELD, jun. "Improvements in chains for coupling, cranes, cables, mining purposes, hoisting, and all other purposes where chains are used." Dated Jan. 5, 1859.

Instead of making chains of single links, it is here proposed to form them of double links, one set being a little longer than the other, so that when any strain is applied the short links only receive it; but should any of the short links break or snap, the longer links then take the strain. *Patent completed.*

43. J. KIRKMAN and I. GRUNDY. "Improvements in certain kinds of bed covers or counterpanes, and other textile fabrics of similar character, and in the mode or method of weaving the same." Dated Jan. 6, 1859.

This applies to fabrics known as Bolton or Mar-seilles quilts, or others of like texture. So far as relates to the fabric or tissue produced, it consists in the combination of a new and peculiar kind of ground with a damask or calico figure. This ground is produced by the intertexture of the binding weft with both parts of the warp. The figure combined with the ground is produced by a double pick of weft thrown in for each card. There are various other features included. *Patent abandoned.*

44. G. BURY. "Improvements in part or parts of apparatus commonly used and applied for effecting the pick in power looms for weaving." Dated Jan. 6, 1859.

This relates to looms in which the picker is ordinarily connected to the picking stick by a cord or leather strap, and they consist in the substitution for the strap of a flexible metallic connection such as an iron chain; and also in the application of a metal ferrule encircling the end of the picking stick. *Patent abandoned.*

45. H. G. COOMBS. "An improved method of constructing railings, bars, gates, gratings, columns, and all other builders' work of a like nature or description." Dated Jan. 6, 1859.

This consists in the application of wrought or other iron or metal tubes, together with iron or other metal fittings, ornaments, or fixings to the same in the shape of caps, bases, crossrails, or otherwise, to be fixed thereto by screws, pins, or rivets, or by heat as required. *Patent abandoned.*

46. E. T. HUGHES. "Improvements in machinery or apparatus for preparing cotton and other fibrous materials to be spun." (A communication) Dated Jan. 6, 1859.

This relates to carding engines, and consists in arranging an additional cylinder to the ordinary carding engine which receives the material to be carded from the feeding rollers, and passes it either direct to the ordinary large cylinder, or through the medium of a breaker. *Patent abandoned.*

47. W. and T. RENTON, and W. BINNS. "Improvements in finishing woollen and other fabrics." Dated Jan. 6, 1859.

This consists in subjecting woollen fabrics, &c., to hydraulic pressure. *Patent completed.*

48. J. ASPINALL. "Improvements in machines for the manufacture of bolts, rivets, and spikes." Dated Jan. 6, 1859.

The patentee claims, 1, the use and adaptation of the direct action of steam or of a hydraulic ram to the forming of bolts, rivets, or spikes, by a blow or succession of blows. 2, the construction of punch boxes and dies, both as described with reference to the drawings. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated June 23, 1859.

1507. M. A. F. Mennons. Improvements in machinery for the manufacture of bolts and rivets. A communication.

Dated July 16, 1859.

1682. J. Bernard. Certain improvements in the manufacture of boots and shoes, and in the machinery and apparatus to be employed therein.

1686. O'D. Grimshaw. Improvements in safety letter boxes or bags.

Dated July 20, 1859.

1706. W. J. and D. Gradwell. Certain improvements in bearings or journals employed in machinery, which improvements are also applicable to the bearings of railway and other wheels and axles.

Dated July 21, 1859.

1714. C. and J. B. Tapp. Improvements applicable to steam boilers and furnaces for consuming smoke and economizing fuel in the generation of steam, and in the apparatus connected therewith.

Dated July 26, 1859.

1734. W. H. Buckland. An improved preparation of peat.

1736. P. D. Mickles. An improved spring for railroad and other carriages, and for other uses and applications where springs are required. A communication.

1737. J. Hinks and G. Wells. An improvement in, or a substitute for, the hook of the ordinary hook and eye dress fastening.

1738. J. Gillott and J. Morrison. New or improved machinery for the manufacture of the handles of pen-holders, which machinery or a part or parts thereof, may also be employed for manufacturing other cylindrical articles.

Dated July 27, 1859.

1740. M. A. F. Mennons. An improved comb-cleaner. A communication.

1742. J. Davies. A new or improved self-adjusting ventilating apparatus.

1744. J. Scoffern. Improvements in waterproofing, cementing, and stiffening fabrics and fibrous materials, and also in dyeing fabrics and fibrous materials.

Dated July 28, 1859.

1746. W. Hudson and C. Catlow. Certain improvements in looms for weaving.

1747. E. Hunt and H. D. Pochin. Improved resin and resinous substances.

1748. A. Sidebottom. Improvements in the mode or process of separating animal fibre from mixed fabrics of animal fibre and cotton or other vegetable fibre.

1749. C. W. Smith. Improvements in electric telegraphs, and in apparatus connected therewith.

1750. W. Kent. A self-acting fan.

1751. J. W. D. Brown. Improvements in signal and lighthouse lamps and lanterns.

1753. W. E. Newton. Improvements in grinding mills. A communication.

1754. W. Clark. Improved apparatus for turning over music leaves or sheets. A communication.

1755. J. Jackson. Improvement in metal pens.

1756. P. Robertson. Improvements in the manufacture of beer, ale, porter, and spirits.

Dated July 29, 1859.

1757. T. Culpin. Improvements in water-closets, water-cisterns, urinals, baths, lavatories, and other sanitary apparatus, and in the mode of supplying water thereto.

1758. I. M. Lindley. Improvements in cop-tubes.

1759. J. Wright. An improved method of raising or drawing up the skirts of gowns or dresses. A communication.

1761. P. A. Viette. Improvements in engraving on metal or on other substances decomposable by acids or corrosive salts.

1762. J. Chandler. Improvements in apparatuses for indicating the water level in boilers and other vessels, parts of which are also applicable for inspecting the interior thereof.

1763. T. J. Terrell. An improvement in ships' riding bits, and "timber heads."

1764. A. V. Newton. Certain improvements in that class of fire-arms known as revolvers, and in bullets for the same. A communication.

Dated July 30, 1859.

1765. J. Wood. An improved truss for hernia.

1767. G. Gurney. Improvements in electric telegraphic conductors.

1769. T. Firth. An improved breech-loading cannon.

1771. A. B. Wilson. Improvements in the manufacture of hats.

1773. P. M. Parsons. Improvements in switches and crossings of railways.

Dated Aug. 1, 1859.

1775. J. Molladay. An improved form or construction of hat, cap, or covering for the head.

1777. T. G. Messenger. Improvements in the construction of buildings or erections to be used for horticultural or other purposes.

1779. J. Howland. An improved apparatus for mashing and mixing.

1781. W. E. Newton. An improvement applicable to salinometer cases for steam boilers. A communication.

Dated Aug. 2, 1859.

1783. J. C. Ashwell. Improvements in wheels for railway and other carriages.

1785. H. Olorenshaw. An improvement in neck-ties.

PATENT APPLIED FOR WITH COMPLETE SPECIFICATION.

1849. G. T. Bousfield. A new and useful method of manufacturing the vulcanized compounds of vulcanizable gums. A communication. Dated Aug. 9, 1859.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

(From the London Gazette, Aug. 16, 1859.)

822. Y. M. Thomas. Propeller.
832. M. Coupland. Furnaces.
850. R. Fairburn. Carding wool.
852. F. C. Bakewell. Fire-places. A communication.

853. G. F. Chantrell and E. Dutch. Water-closets.
855. J. Hetherington, T. Webb, and J. Craig. Spinning and doubling.

856. T. Scott. Fibrous materials.
861. J. Scoffern. Lubricating projectiles.

865. D. Moseley. Carding cotton.
880. N. A. Grumel. Dyeing cotton, &c.

882. T. Barnett, H. T. Sourbuts, and W. Loynd. Steam-engines.

891. J. H. Johnson. Cyanide of potassium. A communication.

895. W. E. Newton. Steam-engines and boilers. A communication.

923. R. Emery. Carriages.
924. W. A. Martin and J. Purdie. Fire-bars.

929. W. Craft and T. Wilson. Pinafors.

938. J. Beattie. Preventing carriages running off the rails.

945. S. Barnwell and A. Rollason. Umbrellas, &c.
943. G. Abeillou. Arching plane.

957. W. E. Newton. Alumina. A communication.
960. H. Harrison. Looms.

985. P. and J. Reynolds. Hackling flax, &c.
991. A. V. Newton. Seamless bags. A communication.

1043. R. Main. Wheels.
1051. J. H. Johnson. Polishing knives. A communication.

1087. W. Clark. Supplying air to diving bells. A communication.

1091. J. Souquière. Distilling coal.
1109. W. Sellers. Screw bolts and nuts.

1204. W. S. Thomson. Skirts. Partly a communication.

1412. W. Sellers. Ovens.
1560. J. Lawson and S. Cotton. Roving, twisting, and spinning.

1580. T. J. Hart. Fire-arms.
1595. C. Barlow. Capstans. A communication.

1628. E. Livermore. Fluids for burning. A communication.

1638. A. Cooper. Grips of swords.
1631. J. Bernard. Pumps.

1682. J. Bernard. Boots and shoes.
1691. J. Bernard. Boots and shoes.

1720. S. A. Bell and J. Black. Fusée.
1759. J. Wright. Raising skirts. A communication.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed August 12, 1859.

493. J. Parkinson.
410. C. Sanders.
414. R. Clegg, F. Angerstein, and J. W. Page.

420. W. Raymond.
421. J. Paterson.
423. G. Bedson.

426. S. Bailey.
428. C. E. Wright.
448. T. Cattell.

447. F. W. Emerson.
443. C. Fay.
461. W. Clay.

462. W. Basford.

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, AUGUST 26, 1859.

BOAT-LOWERING APPARATUS.

MEN and women are not very costly creatures. In this country, at any rate, the propagation of the species proceeds with (to say the least) all due rapidity. Our young people become men and women very early—considering the latitude of the land in which we live—and but few of them are men and women long before they become fathers and mothers. Hence we thrive so in the matter of population that we might well be pardoned for holding human life cheap among us. It cannot be of great consequence to us that a sailor more or less drops into the sea, and is left there. Nay, we may very well be supposed to spare a boat's crew, or even a ship's company, occasionally without much inconvenience. Even a few passenger ships might disappear annually without placing us in any kind of peril or extremity. With several millions of men and women encompassing us here in London alone, we can afford to lose an *Avenger*, a *Birkenhead*, an *Amazon*, an *Arctic*, occasionally. Had the *Eastern Monarch* gone down in mid-ocean instead of the Portsmouth waters, why need we have repined or murmured at her loss?

Considerations like the foregoing must have occurred at times to all of us. Yet there is such an ineradicable love of life in us, and such a dread of the suffering that commonly attends death, that we cannot satisfy ourselves without attempting to reduce those losses of life which are continually appalling us. No wonder, then, that means of lowering and disengaging boats rapidly from ships should have been a favourite subject of study to many minds for years past; for there is good reason to believe that nine out of ten of those who are annually drowned in and from ships might be saved by such means. It is not our present purpose to investigate closely what has been done of late years in connection with this subject. But there are present to our mind a few considerations which seem to require notice just now.

All the boat-lowering and boat-releasing inventions for which the public patronage is just now sought—sought, that is, with any considerable degree of commercial activity—are, so far as we know, three, viz., Mr. Clifford's, Captain Kynaston's, and Messrs. Wood and Rogers's, the last of which was described and illustrated in our pages so recently as the 12th inst. The order in which we have mentioned them is the order in which the three plans were successively brought forward. Now, apart altogether from the relative merits of these systems, there is something to be said of the time and manner of their introduction. Of all the fallacies of inventors—and some inventors cherish many fallacies—there is no more common one than that of over-estimating the commercial value of inventions. It is quite true that every week men are making fresh fortunes out of patented articles, often with but little aid from capitalists, or even from capital. But in the majority of cases an invention, however excellent intrinsically, and although patented, is perfectly worthless in the hands of a man who has neither capital nor the means of acquiring it. This is true even where the novelty has no opposition to cope with. But where an invention affecting vested interests in any unpleasant way is brought forward, no matter what its object may be, the work of carrying it out commercially is inconceivably great and burdensome.

Now, in the practical introduction of appara-

tus for lowering and releasing boats rapidly, enormous difficulties have been encountered. No language that we might here employ could in the least express the amount of lethargy—to say nothing of active opposition—which existed in reference to this subject when Mr. Clifford first sought to give effect to his proposals. The money, the labour, the time, the patience, the determination, the tact, the courage, which were needed, transcend infinitely the merit of producing an efficient apparatus for the purpose. The invention itself, however well contrived, is as nothing in comparison with the efforts expended upon its introduction. For these efforts, made zealously and most persistently, Mr. Clifford deserves, in our opinion, far greater credit than the most meritorious boat-lowering invention could of itself win. To him belongs, and from him cannot be taken, the honour of having not only demonstrated the practicability of saving life by a suitable apparatus, but also of having forced the fact upon the minds of ship-owners, Emigration Boards, Admiralty Boards, and the universal public with such clearness and cogency that the captain who now goes to sea without some such apparatus renders himself liable to the reproach of being guilty of wantonly risking life, should a life be lost for the need of it. Indeed, we hope we shall soon see captains put upon their trial on charges of manslaughter should either seamen or passengers be lost where the sudden lowering and releasing of a boat could save them.

That Mr. Clifford has thus familiarized all minds with this great subject, and caused all to look for an efficient method of getting ships' boats speedily into the water in cases of emergency, is a clear proof of his fitness for the work he has undertaken. It is a mistake to suppose that he was unfamiliar with boats and boating when he began his great and humane work. He was long before known upon the Thames both as a skilful boatsman himself, and as a zealous cultivator of the art of boating in others. He for a long time took the lead in several movements which had the improvement of that art for their object. It is also due to him to say that his plan of lowering and releasing boats, which is now adopted in hundreds of vessels, and which has already saved scores upon scores of lives, was not taken up with haste. We have frequently in times past had opportunities of tracing the successive steps by which he arrived at that plan, and we must say that in his course he devised, tested, and abandoned many schemes which have since reappeared in other places. We state this simply to give him the credit—which is his just due—of not having lightly or inconsiderately sought the accomplishment of the great object he had in view. Moreover, we must add, had nothing higher than a mere pecuniary interest inspired him he would never have done what he has. It is a fallacy to suppose that any mere money-loving man, unless totally ignorant of the world and its ways, would ever turn to the invention of any such thing as a boat-lowering apparatus. It is a sadly fallen world this, and anything like a humane purpose is positively a bar to the adoption of any improvement whatever. A shipowner, in nine cases out of ten, would in reality far sooner effect a saving of one per cent. in his money outlay than 50 per cent. of the lives which he loses. Remembering this, and recollecting also that every apparatus for lowering and releasing boats in a novel way costs money, our readers will not think very highly of Mr. Clifford's pecuniary advantages in connection with his invention. We know, indeed, that many inventions that have not cost their authors a fiftieth part of the expense, time, and personal exertion that have

fallen to Mr. Clifford's lot, are at this moment bringing in fifty times larger returns and profits than spring from his, notwithstanding the extent to which his plan is now adopted. We ought also to say that Mr. Clifford has not shrunk from even greater risks than mere money matters can involve in the furtherance of his design. For the sake of the lives of others he has, as we think, repeatedly risked his own, having often put his apparatus into operation with his own hands under circumstances in which no boat could have been lowered by ordinary means—descending from the ship's side in the roughest weather, and when the vessel has been steaming at her greatest speed.

Having thus attempted to do justice to Mr. Clifford's labours in this great question, we must now observe that, notwithstanding those labours, his invention must stand solely upon its merits, and be prepared, if it is to continue in favour, to compete freely with all others. We do not wish to imply that Mr. Clifford needs to be reminded of this fact. He has, so far as our knowledge of his proceedings goes, always avoided pleading his services, and based his claims upon the merit of his plan alone. In our own pages he has repeatedly avowed that this is the only position which he desires to assume. This is quite as it ought to be; and although it may appear hard that one man should sow, and a host of others rush in to reap the harvest, we are bound to adopt a better invention than Mr. Clifford's, should such be forthcoming.

Next to Mr. Clifford comes Captain Kynaston, C.B., to whom also seamen and the public are greatly indebted for his labours. Captain Kynaston is no imitator of Mr. Clifford, or of any one else. He came home wounded from the Russian war, and in the leisure which followed—if a period of acute and prolonged suffering may be called leisure—gave that professional attention to the subject which Mr. Clifford has continually invited. He speedily came to the conclusion—whether rightly or wrongly—that the method of placing both the lowering and the releasing of the boat in the hands of a single individual on board of her was an improper one; and accordingly set about devising a means of releasing the boat instantaneously after she had been lowered in the usual manner by the tackles by men on board the ship. This means is admirably provided in his disengaging hook, with its arrangement of lines or falls. Having succeeded in inventing this to his satisfaction, the gallant inventor proceeded to urge its adoption on his brother officers with aims as high, and motives as pure, we believe, as Mr. Clifford's. Standing well in his profession, and being personally known to many of its members, he has been far from unsuccessful. Our own columns have shown repeatedly how favourably his plan has been received, and what satisfaction it has given. Recently the Admiralty have given instructions for any captain or other officer in command who may desire to carry the apparatus to be furnished with it. His must be an ill-balanced mind indeed who does not take pleasure in its success. For our part, we most warmly and cordially congratulate Captain Kynaston—who is known to us as a most able man and gallant officer—upon the good result which his cares and labours in this matter have already brought about.

The last labourers in this noble work are Messrs. Wood and Rogers. The former of these gentlemen is an officer of the Peninsula and Oriental Company's ship *China*, who avows that increased efficiency and security in boat-releasing are his objects; the latter is an ex-

perienced foreman of shipwrights in the dockyard of the Messrs. Green, at Blackwall. Our first impression of the plan was, we confess, not very favourable, for it happens that when we were ourselves benevolently contriving plans of our own for effecting this object eight or ten years ago (—we have not invented anything since, let it be understood—) we devised the precise arrangement adopted by Messrs. Wood and Rogers. We then rejected the plan, thinking the long bolts extending along the inside of the boat would be liable to be carried away by the rough usage to which boats are subjected, especially in times of emergency. But we are not disposed to insist upon this objection. Other persons, who are perfectly competent to pronounce an opinion upon the subject, do not urge it. Messrs. Money Wigram and Sons, for example, in writing on the subject, do not mention it, but tell us that the plan “appears to possess the advantage of having no rope as part of the disconnecting apparatus that could kink in running out, and that after the gripes are cast off, the boat hanging at the davits would not cant from a person stepping on the gunwale in getting in; and by having a spare set of the spurs to be attached in the boat, the davit tackles can be hooked on immediately on reaching the ship.” Mr. Joseph Samuda also tells us that he has witnessed a trial of the apparatus, and that “it was in every way satisfactory as regards the merits of the system.”

On referring to our engravings of the 12th instant, the reader will see that Messrs. Wood and Rogers, like Captain Kynaston, lower by the tackles, and release the boat only with the special apparatus. Whether this plan is or is not superior to Mr. Clifford's can hardly, we think, be settled. It appears certain that by Mr. Clifford's system a boat can really be got into the water in a briefer space of time than on either of the other systems; but all can do it in a minute or two, and that may be all that is necessary. For ourselves, we refuse to speak definitively upon this point for the very simple and safe reason that no speech of ours—or, indeed, of any one's—can possibly be received as authoritative on such a subject. Some officers will always, doubtless, prefer to use the tackles in lowering; others will, as doubtless, prefer to dispense with them. It is properly their prerogative to decide the matter, and we willingly leave it to them.

One thing we ask, and one thing we must insist upon, viz., that when so many reliable contrivances for saving life at sea are to be had, shipowners shall not allow the lives of the public to be sacrificed for the want of them with impunity.

OUR RIVER DEFENCES.

CAPTAIN COWPER PHIPPS COLES, of Lady Nancy raft reputation, has thrown a few thoughts together into a printed paper with a view of aiding us in our present schemes for defending our coasts. As this officer takes a somewhat novel view of the subject, and as he brings experience of his own to bear upon it, an abstract of his views may be of service here. It is not invasion to any extent of which we have to be apprehensive, he thinks, but a flying squadron of fast gun-boats, and ships of moderate and light draught of water, that could, after evading our fleet either in a fog or by false intelligence, run up any of our rivers, capture or burn our shipping, and levy contributions upon helpless towns, such as those upon the Thames, the Humber, the Mersey, Tyne, or Clyde. It may be replied—The forts will stop them. His answer is—in these days of steam, when a vessel can go ten knots, with three knots' tide in her

favour, they are incapable of doing so; at any rate, it would take years, and require enormous funds to construct sufficient forts for effectual protection. Moreover, the smoke of the first gun fired from these forts would blind all the others, particularly where any have more than one tier of guns. “Let me ask,” he says, “what chance have you of hitting a flying object going thirteen knots? You are lucky even if every gun gets a hurried flying shot at her, which from the rate she is going at would, unless very well judged, drop harmless into the water astern of her, like an inexperienced sportsman who frightens a rabbit, or perhaps tickles his tail.”

Assuming that our navy may be called away, and our coasts be left for a short period to their own resources, we obviously require, he says, some means of rendering speedy and efficient protection to our wealthy mercantile ports, by means that shall readily be created, but be comparatively inexpensive, comprising the means of a rapid and vigorous expansion, in case of war, and only available for a given locality. The question is, in fact, how are we to protect these rivers and harbours against an enemy's flying squadron? In addition to our present means, Captain Coles suggests the placing of numerous detached guns afloat on each river, in shallow water, where sea-going ships could neither run over nor board them. From the experience he had with the Lady Nancy, at Taganrog, and other ports in the Sea of Azoff, he feels convinced that nothing has been hitherto invented that can excel a raft for the purpose of floating guns into shallow waters. The cost of a raft is but trifling (£100 each), this in itself being a great recommendation; further, it is easily constructed, and possesses great strength, durability, and buoyancy; it also draws but little water, and being made of casks, comprises, as it were, so many water-tight compartments. From this last cause, combined with its lowness, and the small object it would present to an enemy, he believes it would be impossible to sink a raft. “I can testify,” he says, “that rafts of such a construction give a most steady platform, with the great advantage of ricochet firing, and the concussion of the gun does not in any degree affect the casks or the structure, which, if damaged by shot, can easily be replaced or repaired.”

It may be said, If you want to float a number of guns, why not take up all the small steamers, lighters, barges, and other such craft? To these there are, Captain Coles considers, great and manifest objections. They possess none of the powers of endurance against shot that a raft has, besides being immeasurably more costly in their construction; they are likewise less buoyant, and consequently are less capable of navigating shoal water, and present a larger and more defined object to an enemy's guns. Further, as such vessels are not fitted for guns, you would first have to fit them by strengthening their decks, shoring them up, &c.; the masts, too, are badly placed and in the way of the gun. Such craft are also of different sizes, and therefore would each require different fittings, and when complete, and the guns put in, the concussion of firing would start all the caulking, and so strain their timbers that you would at once have a leaky vessel, which would either sink herself, or, when under fire, being in only one compartment, would be sent by the very first shot to the bottom. A raft could be built quicker than one of those vessels could be even caulked, much less fitted to carry a heavy gun.

The cross fire of any number of rafts, when placed in shallow water, and possessing the means of readily altering their positions, no

vessel could escape. But boats will board them, it may be said. In reply to this objection Captain Coles says:—“The success of the attacking vessels depends upon their speed. To lower and man boats they must stop, when the cross fire of these numerous rafts would most likely prevent the boats leaving their ships at all.” It may again be said, they will tow their boats with the men in them already to make a dash. But, “they cannot tow boats fast for fear of swamping them; besides, if they are hit and swamped with a number of men in them, it would cause great confusion, which would be increased every moment she was stationary, by the cross fire on her.”

So much for what may be called the theory of the subject. As to practice we are told by our gallant author that, having already tried and accomplished it, he will guarantee, with a gun's crew, four shipwrights, and a cooper, to put together in twelve hours a raft that will carry a gun of the heaviest calibre. He even gives us the very names and qualities of the materials required for the purpose:—

“All the materials that it requires is, 300 fathoms of rope (rounding), 30 butts, or a greater number of smaller casks, in proportion; 14 fir poles, 45 feet; 24 poles, 20 feet, or a greater number of smaller ones; and 100 feet of 3-inch planking, 2 anchors, hawsers, warp lines, &c. Gun and carriage, with 100 rounds of ammunition, when she will only draw two feet of water.” His mode of putting a raft together is so secure, and at the same time so simple, that any sea-faring people could be taught, he believes, to construct them with great ease, and any one having seen a model, with a little explanation, would be able to build one.

It may not be out of place here to explain how Captain Coles would make these rafts available, and organize them as a regular system of defence for our maritime ports and towns, and wherever there is shallow water. At such places, during peace, he would have established an officer and gun's crew of gunners, instructed in building these rafts. It would be their duty to build one or more, on which guns would be mounted, and to teach any number of volunteers who could be induced to learn the gun drill and to build the raft. With a little encouragement, all the population connected with shipping, such as boatmen, piermen, lightermen, and shipwrights, would, it is thought, willingly give up a certain time to this for a slight remuneration at the expense of the town to be protected. By having a large number of these men taught and trained, you could man any number of guns, having in each an experienced gunner for captain. In case of our shores being threatened, or any emergency arising, swarms of those rafts would spring out of every river and creek, the Government merely finding the guns and ammunition, of which a store should be kept near a pier, where each raft could arm as fast as it was built. The numerous tugs would then tow them into position to the shallow waters of our rivers, which “in a miraculously short space of time would be literally lined, as well as thoroughly defended.” These rafts being by comparison almost inexpensive, and at every port at once offering a self-created defence, our men would be organized and told off into regular gun's crews, and with a little tact and practice a healthy emulation would be evoked, strengthened, and perpetuated; so that in the event of a war, we should have a most effective body of floating coast artillerymen at all times ready for service on their own coast. The possession of such a force would give assured

confidence to the country and discouragement to the designs of an enemy.

So many considerations come in to check one's approbation of plans like this, that we do not think it wise to pronounce at once in favour of the adoption of these proposals to any great extent. But we are quite prepared to ask with Captain Coles,—Is it not at all events worth while to try a few of those rafts, to show what capabilities and powers they possess? If they fail, the expense is trifling; if they succeed, how cheaply we can augment our protection in case of war!

THE PURIFICATION OF THE SERPENTINE.

THE plan proposed by Mr. Hawkesley and adopted by Mr. Fitzroy for improving the condition of the long pond in Hyde Park and Kensington Gardens—yclept, on the *lucus a non lucendo* principle, the Serpentine River—appears to have met with unqualified disapprobation from the public press and the greater portion of the engineering profession. On the other side, however, we have the names of Mr. Robert Stephenson and Mr. T. Spencer; and the analytical experiments of the latter gentleman are certainly not without weight in favour of Mr. Hawkesley's scheme. This scheme consists in drawing about 2,000,000 gallons of water daily from the lower end of the lake, and throwing the same, when freed from mechanical impurities, into the upper end in the form of a cascade. The effect of this flow of aerated water would be to oxidise the soluble organic matter that nourishes the growth of the *confervæ* and slimy vegetation, which are so detrimental to the appearance of our ornamental sheets of water. It is not, therefore, upon the filtering process alone that we are to depend for the removal of objectionable impurities, and for the attainment of a comparative degree of limpidity. The stagnant vegetation is to be attacked both by natural and by artificial means; since the former cannot wholly be adopted. The importance of the "cascade" during the prevalence of close and dry weather is not easily to be overrated. The chemist can testify to the danger which would be incurred, even in the absence of sulphur and phosphorus from the dissolved organic matter, by removing the living vegetations in whose growth this is absorbed, without at the same time supplying nature's great purifier, oxygen, to obviate chemical changes of a more dangerous character than the conversion of this organic matter into carbonic acid gas. And although it may be observed that this gas is one of the principal supporters of vegetable life, yet the plants which thrive in aerated water are of a very different class to those which grow so freely in a semi-putrid and stagnant compound of decayed vegetable and animal matter.

The necessity both of filtration and aëration is strongly exemplified in the present condition of the lake in St. James's Park. The process there adopted is characterised by the *Times* writer, who so strongly repudiates Mr. Hawkesley's plan, as a "complete success." But surely this gentleman cannot himself have verified the condition of this piece of water, or the expressions "clear" and "limpid" must be intended as ironical. We leave the question of their applicability to any of our readers who have an opportunity of viewing the result of the experiment by which this lake has been rendered so completely artificial. Unless much wind or rain shall have intervened, they will find the greater part of it covered with a thick and apparently solid slime—a crust supporting multitudinous light bodies; while throughout

its whole extent the flocculent *confervæ* arrest the sun's rays before their warmth can be absorbed by the solid concrete below. Upon this concrete the vegetations will ultimately be deposited in the form of mud.

Much stress is laid by the advocates of the system adopted by Messrs. Easton, Amos, and Co., in the St. James's Park water, upon the nuisance likely to arise from the filtering apparatus to be established at the upper end of the Serpentine. But if any such nuisance occurs it must be from gross negligence or want of skill. The matters to be separated are neither poisonous nor rapidly putrescent. The mud at the bottom of the Serpentine is, as we are assured by Mr. Spencer, very different from the Thames slime, the offensiveness of which is owing to a black substance composed of sulphur, carbon, and iron, of which no trace is found in the lake. Choleic acid from bile, and sulphuretted hydrogen evolved from sewage matter, are also absent. Indeed, the impurity of the Serpentine water has been much exaggerated, despite the occasional overflow into it of the contents of the Ranelagh sewer—evidenced at rare intervals by the presence of *paramécia* and *vibriones*. Its offensiveness is simply that of ordinary stagnant water, arising from decaying vegetation, and is far more perceptible to the eye than to the organ of smell. To remove this water, amounting to 60,000,000 of gallons, and to replace it by a similar quantity exposed to the same conditions of stagnation, would be an evident absurdity; and the formation of a shallow artificial bottom of concrete is, in our opinion, not likely to improve its quality. The depth of water in the Serpentine is an advantage the result of which in preventing the most objectionable forms of vegetation has been generally overlooked; and the carbonaceous bottom would probably be but ill replaced by a concrete, the deposit upon which would ferment in the direct rays of the sun.

With regard to the filtering process it may be observed that the method to be adopted will be similar to that in use at the Glasgow Gorbals Water-works, and other establishments of the same nature. The simplicity and efficacy of this method have been fully tested. The water is discharged from the conduit on the top of a compartment of gravel, through which, by means of an aperture at the bottom, it passes into a well adjoining. The overflow from this then runs into coarse sand, and in a similar manner into fine sand, before it is ultimately discharged. In the case in point there will, for convenience of cleansing, be two such filtering contrivances; and one or more of the stages of purification may probably be dispensed with.

To remove the impression which appears to prevail that the water in the Serpentine approximates in its characters to that of the Thames, it would suffice to examine comparatively the deposits of lime on the margin of the lake and on the banks of the river. That from the latter will be found soon to evolve its noxious constituents; while the lime deposit from the Serpentine is wholly inoffensive. In both cases the addition of lime is of very questionable utility. In the Serpentine especially, though it destroys the *confervæ*, together with the animalcules and the fishes, it cannot prevent their putrefaction, or remove its products. When the plan of Mr. Hawkesley shall have been carried out, we hope that these organisms will be left to fulfil, under more favourable conditions, their due purposes in the economy of nature, and that the Serpentine, when restocked with fish, may afford, as of old, a harmless amusement to the piscatorial enthusiasts of London.

THE MAIN DRAINAGE SCHEME.

THE ground which we take in decrying the main drainage scheme is, we think, perfectly open to us. The greatest chemists in the world tell us that the soil must be replenished, either by the waste portions of human food, or by some substitute for it; and we know perfectly well that the use of guano, and other artificial modes of restoring the soil's energies, are very costly. We know further that no mechanical impediments prevent us from returning to the land that with which we at present pollute our beautiful and noble river. Why then, we ask, with these facts before us—why are we spending millions of pounds sterling on a scheme which is designed still to deprive the land of that which it so much needs, only to pour it into a river that refuses even to absorb it uselessly?

In our number of the 12th of August, we devoted a column or two to the repetition of this question, and by doing so have brought down upon us the rebuke of a journal which, as it is both temperately and ably conducted, has a perfect right to speak upon this or any other great public question. It is the *South London Local Journal*—which circulates freely from Richmond to Woolwich, and from Southwark to Croydon, and even beyond these limits—that has, not undefiled, parried the blow aimed at the Board of Works. To show that he is not unfriendly to us in the main, our antagonist thus commences his remarks upon our article:—"We regret to see that the mania against the Board is not confined to the less influential portions of the press. Our excellent contemporary, the *MECHANICS' MAGAZINE*, in its issue of last week, contains an article which inveighs against the Metropolitan Board without one word of qualification. The increasing reputation of this well-conducted Magazine, gives peculiar weight to its advocacy or opposition. The public principally owe to it some important reforms of recent date, and will probably be indebted to it for several more. If this one organ had defended the upper Board against its opponents, we should have felt that public opinion was likely to receive a salutary influence in an important quarter. But the editors of the Magazine in question are fully equal to their contemporaries in the weight of their denunciation." After this flattering commencement, we were not, of course, to be rebuked with bated breath. Hence, we read:—"It may sound very well for a scientific periodical to rail at the Board for not utilizing the sewage, but the Board in return may complain that while science talks of the value of the sewage, no practicable method has yet been devised by which the value can be realised. The waters of the sea may hold silver in solution, but by what process are we to extract it at a commercial profit? The theory may be excellent, but where is the practical method? The Metropolitan Board is not a conclave of engineers. All they can do is to take advantage of the scientific talent of the day. But where is the plan which provides for the accomplishment of that which the foregoing extract demands of the upper Board? We candidly confess that we once advocated a plan different from that of Mr. Bazalgette, but in so doing we abstained from condemning the scheme of the upper Board. Our argument then amounted to this—that while Mr. Bazalgette's plan might answer the purpose, there was a cheaper method which might be less complete, but which would be also less expensive, and which would accomplish all that was really required. No such moderate opposition will satisfy the present temper of our contempo-

"varies in general and the MECHANICS' MAGAZINE in particular."

Now, we are not in the least angry with our friendly contemporary for saying all this; but we desire, nevertheless, to show in a few words that he is scarcely fair to us in his observations. In the first place, although we claim the right to speak occasionally of an evil without pointing out in every case the remedy, it happens that in the article criticised we were not dumb on this head. We referred, for example, to what is going on at Paris. We stated that the intercepting sewers on either side of the Seine are already finished, and that arrangements are in progress for deodorising their contents, which are to be applied to the land, as they ought to be. We also referred to the plans of Mr. F. O. Ward and Mr. G. Coode; and we then contended, as we are prepared to contend again now, that it is not from want of knowledge that the Main Drainage Scheme is allowed to be carried into effect.

In the next place we have been, and are, content with that "moderate opposition" for which our contemporary asks. Our position is precisely that which he confesses he once took, for we merely advocate plans different from that of Mr. Bazalgette without "condemning the 'scheme of the upper Board'"—without condemning it, that is, in any other way than that of opposing the waste of agricultural material which it involves. And surely no intelligent writer can refuse to condemn the plan to this extent; certainly the able editor of the *South London Local Journal* cannot avoid so natural an act. We do not deny that Mr. Bazalgette's system will relieve London of most of the poisonous cloud which now rises visibly and tangibly from the foul stream that creeps through it. But we do lament that a mode of relief has been adopted which will do nothing towards the other great ends to which the finger of science has for a long period been pointing, and which, with our present expenditure, might certainly have been attained.

WORKING MEN'S POETRY BY THE POET LAUREATE.

MACHINERY is the chief subject of these pages; a great subject; grand as Nature herself. The first thought of the inventor of a machine is an inspiration, akin to the first thought of the Maker when He planned the organism of the tree or the animal. The same subtle forethoughts, provisions, checks and counterchecks, that entered into the construction of the animal organism enter into the construction of a machine. The laws that enter into the working of a machine are the laws that penetrate Nature's framework. The uses and ends of machinery are a farther development and extension of Nature's aims and ends. The stroke of the hammer, the throb of the engine, the plash of the steam-ship's paddlewheels, make music as true as the beat of the heart, the murmur of the ocean tides, or the song of the morning stars singing together for joy.

This will not sound as rhapsody to those who have really thought about human activities and human civilisation. But great as machinery is, surely the man working the machine is greater. We conceive that especially he, the manual labourer, the mechanic, ought to be a subject of prominent interest in these pages; and that if at any time we dwell on what is peculiar to his condition, and especially on what helps him to realise his manhood, as apart from and superior to his condition, our readers will thank and not blame us.

Reading the other day—as thousands of the best in England and elsewhere have been doing—Tennyson's "Idylls of the King," and feeling

throughout how emphatically an every man's book it is, we determined to make it the subject of a few thoughts on poetry and the working man, or rather literature as belonging to man as man. Books form quite a world by themselves. Seen from our rough, actual world, they are as a celestial city, a city in the air—like that which John of Patmos saw. As in modern Rome, in the common street or shop, some column, or arch, or niche of old Roman fabric looks out on you and reminds you of grander men and times, so from the shelves of our common walks do books look out on and admonish us. All that makes up the solid real world is in the world of literature, but transfigured and glorified. There is the outer life of man there, real, as it is; but all interpreted by the light of the ideal—the light of man's highest aims and desires. There is the inner working of the mind of man there; but of man at his best—the ideal, the true man.

As an example of this high ideal character of true literature, observe the absence in it of all the stigmas and badges of conventionality by which men are labelled in actual life. It deals only in things that have an intrinsic, universally human interest. It does not belong to the rich man or the poor man, the prince or peasant, but to all of these. It sets value only on man as man. It treats of the constituent parts of human nature; of its inborn attributes. It treats of the whole range of universal human existence: of birth, death, youth, maiden, man, woman, infancy, and old age; of work and manners, love and hate, hope, struggle, disappointment, tears of agony, tears of rapture.

If this universality be the test of admission into the commonwealth of literature, then the writings of Tennyson take rank among the highest there. The choice of the subject of his new Poem—the English Knighthood of the Middle Ages—arose out of the Poet's excessive manliness. Here is another child of nature, in an over-civilised time, sighing after the earlier, simpler, more primitive ages. Every stage of healthy development has doubtless its own virtues and beauties. Childhood is so uniquely beautiful that we would fain arrest its growth and fix it as it is. The man smiles at the follies of his youth, but what would he give to bring back the fulness of its energy and joy. It is so in the growth of the human race. Who does not exult at the achievements of civilisation—our noble human dwellings, enriched with the products of every zone; our rapid intercommunications of city with city, nation with nation; our social refinements and charities; our social and civic organisms and liberties; our accumulated wealth of things material and things mental, contributed by the genius of every place and time. But amidst all this gain, how much has been lost? Waited on everywhere and in everything, we lose our energy. The policeman protects us at home, the soldier abroad; and we are afraid of pain or the sight of blood, of risk or danger. But what is worst of all, we are infinitely afraid of this thing we glory in—civilised society. Like a fly with a thousand eyes, each watches society on every side—what does it think of me?—of my house, furniture, dress, manners? what of my opinions, about the mind within me and the eternity behind and before me? Thus are energy, self-reliance, self-help, and daring forfeited for our civilisation. This thought preys like a sickness upon our noblest men. This drove the great Goethe to reproduce the rude, self-helping "Goetz with the Iron Hand," and this we fancy has led our Tennyson to "The Knights of the Table Round."

The language of this book is the pure, crisp Saxon mother-tongue of us all. The natural

scenery described in it is plain English scenery, such as lies close to our own doors. Bodily strength and prowess are revelled in here;—the "knotted column" of the warrior's throat,—

"The massive square of his heroic breast,
And arms on which the standing muscle sloped,
As slopes a wild brook o'er a little stone,
Running too vehemently to break upon it."

Here are natural beauty of face and figure, which are as thick sown amongst the poor as the rich; and more, as the poor far outnumber the rich. Constitutional bent is hinted at as the mysterious ineradicable source of all nobleness or baseness:—

"The world will not believe a man repents:
And this wise world of ours is mainly right.
Full seldom *does* a man repent, or use
Both grace and will to pick the vicious quitch
Of blood and custom wholly out of him,
And make all clean, and plant himself afresh."

Manners are a great subject of the "Idylls, as always with this poet. He is a great worshipper of all that is high-minded, chivalrous, dignified, sweet, and graceful. His stately, heroic soul loathes the meannesses and paltrinesses of his time. He has not lived in vain, if only for the beautiful manners he has taught us. But the manners he teaches are not those of the boarding-school and drawing-room; but the natural, necessary outflowings of a high and beautiful mind:—

"For manners are not idle, but the fruit
Of loyal nature, and of noble mind."

There is one element that perhaps more than any other divides the great from the humble in society, which he singles out and deals his sharpest strokes upon, and that is—scorn. For example, of Lancelot at the homely castle of Astolat, he says:—

"Then the great knight, the darling of the court,
Loved of the loveliest, into that rude hall
Stept with all grace, and not with half disdain
Hid under grace, as in a smaller time,
But kindly man moving among his kind."

And again—

"..... in those days
No knight of Arthur's noblest dealt in scorn;
But, if a man were halt or hunch'd, in him
By those whom God had made full-limb'd and tall,
Scorn was allowed as part of his defect,
And he was answer'd softly by the King
And all his Table."

There is a great deal about poverty and riches in this book. No shame belongs to "honest poverty" here. Perhaps the best thing in the book is the story of a house of broken fortunes which Geraint, a Knight of the Table Round, lights accidentally upon. Geraint rides up to this castle in decay:—

"There musing sat the hoary-headed Earl,
(His dress a suit of fray'd magnificence,
Once fit for feasts of ceremony) and said:
'Whither, fair son? to whom Geraint replied,
'O friend, I seek a harbourage for the night.'
Then Yniol, 'Enter therefore and partake
The slender entertainment of a house
Once rich, now poor, but ever open-door'd.'"

While waiting in the castle court, the voice of Enid, Yniol's daughter, rings clear through the open casement of the hall, singing:—

"It chanced the song that Enid sang was one
Of Fortune and her wheel, and Enid sang:

"Turn, Fortune, turn thy wheel and lower the proud;
Turn thy wild wheel thro' sunshine, storm, and cloud;
Thy wheel and thee we neither love nor hate.

"Turn, Fortune, turn thy wheel with smile or frown;
With that wild wheel we go not up or down;
Our hoard is little, but our hearts are great.

"Smile and we smile, the lords of many lands;
Frown and we smile, the lords of our own hands;
For man is man and master of his fate.

"Turn, turn thy wheel above the staring crowd;
Thy wheel and thou are shadows in the cloud;
Thy wheel and thee we neither love nor hate."

We dare not comment on this song, sung thus amidst ruined fortunes. To us it is as wild and grand as the old Greek legend of Prometheus on his rock. It utters for us the one grand distinction between the little and great,—the noble and the ignoble, the worldlings and the religious of mankind.

Geraint, entering the decayed hall, found the aged mother in "dim brocade," and near her Enid, "in faded silk," looking out (says the poet in one of the purest outbursts of the imaginative power) from amidst this ruined house, and aged, faded parents,—

..... "like a blossom vermeil-white,
That lightly breaks a faded flower-sheath."

She discharges for Geraint the services that look strange to us in a lady. But she knew that whatsoever is fit for human hands to do can never degrade the hands of any doer of it, be they a lady's or a servant's. She took Geraint's charger to the stall, and gave him corn; went to the town to buy flesh and wine;—

"And then, because their hall must also serve
For kitchen, boil'd the flesh, and spread the board,
And stood behind, and waited on the three."

Geraint, before he had seen her, while listening to her song had said to himself,—

"Here, by God's grace, is the one voice for me."

And seeing her so sweet and serviceable, and letting his eye follow her, or rest on her at her lowly handmaid-work, he longed to make her his true wife, and before the night was spent petitioned Yniol for her. Then the heart of the old man, who, whatever evil happened to him, "seemed to suffer nothing, heart or limb," but could endure it all most patiently,—

"Then, howsoever patient, Yniol's heart
Danced in his bosom, seeing better days."

Tennyson has never been poor, but you might think he had from these scenes. Goethe, who never was poor, makes one who was so say, "The fortunate man does not believe that miracles still happen; for only in misery does one discern God's hand and finger, which leads 'good men to the good.' Only he who has been at his uttermost, in mind, body, or estate, has felt his heart run over with trembling joy and gratefulness.

And Geraint wishes Enid to go with him to Arthur's court in the faded silk she wore when he saw her. And Guinevere, Arthur's Queen, who had said to him,—

"But ere you wed with any, bring your bride,
And I, were she the daughter of a king,
Yea, tho' she were a beggar from the hedge,
Will clothe her for her bridal like the sun,"—

met them at the gates, embraced Enid with all welcome as a friend,

"And did her honour as the prince's bride,
And clothed her for her bridal like the sun."

THE GREAT EASTERN.

In a speech made at the general meeting of the shareholders of the Great Ship Company, Mr. Jackson, M.P., made the following remarks respecting the recent completion of this noble vessel—"Bearing in mind," he said, that "Mr. Scott Russell had the completion of the great engine in his hands, and that no other man could have finished it, they were therefore in his hands, but they sent for Mr. Russell and, after great doubts and great deliberation, it was agreed that he should have the work, on condition that the contract should be taken in block; that the pattern card should be the Cunard line packets and the Royal Mail Company's vessels, that the ship should be fitted for 600 passengers only at first, and that the internal

fittings should be subject to the approbation of Mr. Robert Macalmont, who kindly undertook to superintend that part of the work. He (Mr. Jackson) then said they must have abundant security for the performance of the contract. Well, they had the security of Mr. George Wilde that the contract should be duly executed, and they had a reference to three referees of the highest authority, with that of Mr. Macalmont, for the internal fittings. And now, instead of the work occupying six months, as Mr. Brunel anticipated, it had been completed in four months, during which time as much work had been done as was required in building a 120-gun ship. He said if any man retrieved a position, and came out gloriously, it was Scott Russell. The work that he had done was incredible. Such an example of what could be effected by the combination of mind and muscle was unsurpassed. The pattern-card, as he had said, were the ships of those two great companies, and they had the reference to the three men he had named to them, with Mr. Macalmont, for the internal fittings, as to whether the work had been properly performed. Not an hour had been lost upon the work; every precaution had been taken. They brought their capital within a few thousand of what they had told them would be required for the completion of the ship, and it was his belief that if they had put the work in any other hands the ship would not have been ready for sea till next spring, and that she would not have come out under £150,000. Their efforts had been hourly and daily exerted for the success of the undertaking. Their chairman even slept on board. He had never seen a man so devoted to an object as Mr. Campbell was to that. He had no children, and he made the ship his child. His efforts were as untiring, and his zeal as strong as ever, and soon he would see his zeal repaid in the success of the ship. He (Mr. Jackson) was now separated from his wife and family at a time when he looked for recreation, after six months' attendance in Parliament, for having accepted a duty he felt he ought to go through with it. But he should be glad when he was able to withdraw, and it would be a proud day when he saw the ship go to sea, and could feel, with his colleagues, that they had done that which others had failed in doing."

Jury Case.

KEMEN'S PATENT FOR POLISHING COTTON THREADS.
Northern Circuit, Liverpool, Aug. 19.

CIVIL COURT.—(Before Mr. Justice HILL and Special Jurors.)

KEMEN v. LIDDLE.

Mr. Wilde, Q.C., Mr. Webster, and Mr. Theodore Aston were counsel for the plaintiff; Mr. Edwin James, Q.C., and Mr. Hindmarch for the defendant.

This was an action for the infringement of a patent for polishing cotton threads by the application of friction to the threads when in the hank, and while in a state of tension, by means of brushes. The defendant, by his pleas, denied the infringement, and also alleged that the plaintiff's invention was not new, that it was not properly described in the specification, and that it was not properly the subject of a patent. The plaintiff is a manufacturer at Eccles. His machine effected its object by passing the hank (which had been previously dipped in size and squeezed) over two rollers, which were turned with considerable velocity. Against the hank, thus distended and revolving, a cylinder, armed with brushes, and turned with a much greater velocity than the hank, sharply brushed. The effect was to make those threads which had slight excrescences to twist and gradually to absorb into their whole length the excrescences. A high polish was given to all the threads, which also became by the heat of the friction perfectly dry. The polished thread thus produced was easier to sew with, and when worked up with a little silk make a very fine silk-fabric, equal in appearance to a fabric containing

20 or 30 per cent. more silk, but in which ordinary unpolished cotton was used. On the 8th of this month the plaintiff and his attorney inspected under a judge's order, the defendant's mill at Middleton. Two machines were first shown to them, identical in principle with the plaintiff's, and the only difference in detail being that there were, instead of one, two sets of rollers on which the thread was spread, and that teasels were used instead of brushes. Afterwards several other machines were shown by the defendant, in which brushes like those of the plaintiff were used. Notice had been given by the defendant of three or four patents for the same invention as the plaintiff's, but these, it was contended, were essentially different.

For the plaintiff, Mr. Fothergill, the engineer, and several other witnesses were called, by whose evidence it appeared that the chief merit of the plaintiff's machine was its high velocity and great friction applied to the thread, which thereby became very compact and bright, and greatly resembled silk.

Mr. James, for the defence, contended that, although the plaintiff's machine might be more complete and effective than any other, particularly in the speed with which the brush cylinder was made to revolve, yet that, so far as the principle of his invention was described and claimed in his specification, which was the brushing of distended hanks of cotton thread, so as to render it smooth and polished, such invention was not new, but had been long previously to his patent known and used. The learned counsel called Mr. Ireland and several other witnesses, who spoke to having used so far back as 1823 a ruder machine than the plaintiff's, but which did polish by means of brushes fixed to a cylinder hanks of cotton thread distended on rollers. A model of this old machine was produced, but it appeared to have been only recently made from the description of some old persons who remembered the machine.

Mr. Wilde having replied,

His Lordship summed up, and left the jury to decide,—1, Whether the invention was new; 2, Whether the plaintiff was the true and first inventor; 3, Whether the specification was sufficient. The infringement was admitted by the defendant's counsel. Upon the plea that the invention was not the proper subject-matter for a patent, his Lordship should direct a verdict for the plaintiff. The learned judge thought that the defence rested mainly upon the evidence given as to the prior use of Ireland's machine; but the proof of its nature depended mainly on the accuracy of the memory of an old witness as to what he saw when he was a boy. The machines which had been previously patented were different from the plaintiff's.

The jury, without retiring from the box, gave a verdict for the plaintiff, thus establishing the validity of the patent.

Captain George A. Halstead, R.N., Secretary at Lloyd's, attended on Saturday at the Underwriters' offices, in the Royal Exchange, and witnessed a trial of Mr. Ward's Ocean Marine Telegraph, recently tested at Woolwich Dockyard, and ordered to be adopted in the Royal Navy. The experiments, which were highly satisfactory, were terminated by the inventor announcing to the meeting his having received the satisfactory information from America, since his arrival in this country, that the Ocean Signal Telegraph, as then exhibited, had been approved by the New York Chamber of Commerce, and, consequently, adopted by the American navy exclusively.

The Great Eastern Steamship is expected to leave Portland, near Weymouth, on her trial trip, about the 8th proximo, and will return to Holyhead. First-class passengers only will be taken. Tickets, £8, £8, and £10, according to cabin, including provisions, are being issued at the offices of the Great Ship Company, King William-street. The ship is appointed to leave Holyhead, for Portland, U. S., on the 15th September. First class passengers only will be taken on this occasion also. Passage-money (including steward's fee and provisions) £18 to £25; state cabins extra. Return tickets will be granted on liberal terms.

LAYING-OFF;
OR,
THE GEOMETRY OF SHIPBUILDING.
No. VII.

STERN TIMBERS.

WE have seen that the cant timbers extend downwards to the deadwood, which being an integral part of the mass of timber running throughout the length of the ship, and forming, as it were, its backbone, offers a firm foundation for them, and is capable of receiving good bolt fastening through their heels. A considerable opening is left between these timbers at the heads or upper ends, but the length of the surface of the ship is so much reduced below, that it is necessary, in order to allow them all to run down to the bearding line, not only to bring their sides in contact with each other at their heels, but to narrow them considerably. By this means a heeling can be obtained on the deadwood and apron for all the timbers in the fore cant body. But the number and direction of the timbers required to form the stern make it impossible to do this in the after body. The cant timbers are therefore worked as far aft as is convenient, and the remainder of the stern is formed in another way by what are called *stern timbers*.

In the old square-sterned ships, the interval between the last cant timber and the stern-post was framed, below the load water-line, by means of horizontal cross timbers called *transoms*, and beneath them by short vertical chocks. The aftermost cant timber, to which the arms of all the transoms were attached, was called the *fashion-timber*. Resting upon the upper or wing-transom, and against the after-side of the fashion-timber there was another timber which extended up to the gunwale of the ship and formed the angle between the stern and the quarter; this was the outer stern timber, and was known as the *side counter timber*. The space between it and the fashion-timber was occupied by short vertical timbers stepping upon the side of the former timber; and the stern itself was framed by timbers with straight sides stepping on the wing transom and extending up to the gunwale. Under this system of construction all the external planking of the sides and bottom terminated in rabbets at the side counter timber and the wing transom.

The main characteristic of the modern elliptical sterns is the continuance of the planking of the sides quite round the stern, so that there is in them nothing corresponding to the side counter timber. All the timbers abaft the last cant timber which runs up from the deadwood to the gunwale, are called *stern timbers*. They differ from the cant timbers in this important particular, that whereas the latter are always vertical, the stern timbers are always inclined inwards at the head, so that the planes of their sides never cut the sheer plane in vertical lines as those of the cants do. The amount of this inclination is determined by that of the sides of the ship called the "tumble home;" the necessity for it arises from a regard to the appearance of the stern windows or lights when viewed from aft. If, while the sides of the ship are seen to incline inwards as they rise, the lights were vertical, and the upper ones as broad as those below, the effect would be very disagreeable. All the timbers framing these lights are therefore made to incline more and more as they leave the middle line (where they are upright), until they reach the sides where they have the "tumble home" of that portion of the side. By graduating the inclination in this way all the sight lines of the timbers, and therefore the sides of the lights, appear to be directed to one point above the stern. At the base of the stern there is a curved line called the *knuckle*, formed by the intersection of the upper portion of the stern and the buttock. At this line the after-ends of the plank of bottom terminate, all the plank above it being bent round the curve. It is generally situated at the height of one of the decks, and its projection in the body plan coincides with that of the upper surface of the beams on that deck. Its horizontal projection is not strictly elliptical, but

it approximates to that shape. Its curvature is determined by the constructor with regard to the required fullness of the after-part of the deck. The knuckle line forms, as we have said, the base of the stern, which is strictly a conical surface—this line being the directrix. The fixed point through which the generating lines are to pass is at the height required to give the inclination of the lights just spoken of, and it lies also in the prolongation of the line defining the rake of the stern, or of the after-boundary of the sheer plan. The point thus found is the vertex of the cone which envelopes the stern.

Those portions of the outer edges of the stern timbers which lie above the knuckle, and in the conical surface, are straight; and their projections on both the planes of projection are, therefore, straight lines, but below the cone they follow the contour of the buttock. As the planes in which the sides of these timbers lie pass through the vertex of the cone, they are necessarily inclined to the horizontal plane, and the horizontal projections of the curved portions of the edges of the timbers will therefore be curved. If these inclined planes are parallel to the axis, as they are in some cases, the vertical projections of the curved portions of the edges upon the body plan will be straight lines—continuations, in fact, of the projections of the upper parts; but, if the planes cant inwards, then the projections upon the body plan, as well as upon the half-breadth, are curved below the knuckle. The former of these cases but rarely occurs. When it does, the mode of finding the true shape is very simple. Draw in the body plan, in the required position, a straight line, leading up to the vertex of the cone, and cutting the level lines below the knuckle. Measure the distances of its points of intersection with the sheer lines and level lines from the middle line, and set them off in the half-breadth on the corresponding lines, by which means the horizontal projection may be obtained. Then square up these same points into the sheer, and obtain on that plane another vertical projection of the moulding edge of the timber. Now, suppose the plane containing this moulding edge to be swung round a horizontal and fore-and-aft line passing through the knuckle until the plane is parallel to the sheer plane. In this revolution every point in the edge of the timber will move vertically—those above the knuckle upwards, and those below it downwards. Those points, therefore, which have been projected on the sheer plan from the sheer and level lines, will be found vertically over or under their projections, and at distances above or below the knuckle equal to the distances of their projections on the body from the intersection at the knuckle. On joining the points so formed we obtain the true shape of the moulding edge of the timber. Proceed in the same manner to obtain the projection of the bevelling edge on the sheer plan, remembering that in the revolution the plane of the bevelling edge must turn about the same axis as that of the moulding edge, so that the distances to be set above or below the knuckle to obtain the true shape must be measured, not from the point in which the projection in the body cuts the knuckle, but from a line, drawn from the point in which the moulding edge cuts the knuckle, and square to the projection of that edge. Sometimes there is an angle in the side of the timber at the knuckle, and the lower part of the timber is parallel to the sheer plan. The vertical projection of this portion of the timber would then, of course, be the true shape.

In the second case—i.e., when the side of the timber is canted—the problem becomes more difficult. According to the only mode that has ever been adopted for laying them off, the positions of their heels cannot be determined beforehand, so that it is difficult to make a good arrangement of the timbers with regard to the short cant timbers below upon which they have to abut. Partly on this account, and partly also as a means of getting better conversion by using timber with a side curvature, the positions

of the timbers of the stern are sometimes determined at the ship, and moulds are made there without the aid of the draftsman. This much, however, is certain, that the side of the timber can always be so canted as to bring the heel wherever it is required. Sometimes the cant necessary for this purpose may give too great bevelling to the timber. Should this ever be so, the timber must be cut with a side turn. In such a case the draftsman's art fails. But it is believed to be always possible to make a good arrangement of the stern frame with straight-sided timbers. Let us proceed to show how this may be done. The method in use will be given afterwards.

New Mode of Laying-off Canted Timbers.—In the diagrams before us, the vertical plane of projection is taken a little on the fore-side of the knuckle; and the horizontal plane of projection is made to coincide with the plane of one of the level lines (No. II.), for a purpose which will be apparent as we go on. On these two planes, we have the projections of the knuckle and roughtree lines, and of the level lines I., II., III. Let $(a, b, a' b')$, $(c, d, c' d')$, and $(e, f, e' f')$ be the upper portions of the moulding edges of three stern timbers. These portions of the projections of the timbers are obtained by fixing their positions on the knuckle, and drawing lines in both planes, leading to the projections of the apex of the cone. We must now proceed to find the projections below the knuckle, for which purpose it will be necessary to discover the traces on the two planes of projection of the plane of the moulding side of the timber. Take, for example, the middle one of the three timbers shown; then we must find a plane which contains the line $(c, d, c' d')$. The horizontal traces of all the planes which satisfy this condition must contain or pass through the horizontal trace of the line, and their vertical traces must contain the vertical trace of the line. Produce $c d$ and $c' d'$ — g will then be the vertical projection of the horizontal trace of the line, and g , obtained from g' , its horizontal projection. Similarly, i is the horizontal projection of the vertical trace of the line, and i' , obtained from i , its vertical projection. The horizontal and vertical traces of the plane must therefore pass through g and i' respectively. There are evidently an infinite number of lines which could be drawn through these points, as there are an infinite number of planes which could be drawn through $(c, d, c' d')$; and it is necessary to decide upon the direction in which the plane of the side of the timber shall lie. The horizontal trace may be drawn, if we choose, at right angles to the curve of the knuckle: in which case the horizontal section of the timber at the knuckle would be square; or it may be desirable to bring the heel of the timber upon the head of the cant timber, s , without regard to the bevelling. In that case mark a point, h , upon level line II., in such a position that a line passing through d and h may fall on the head of s ; then if the line B be drawn through g and h , the horizontal projection of the edge of the timber will also pass through h , because level line II. is in the horizontal plane of projection. The line B , thus drawn, is the horizontal trace of the plane of the moulding side of the timber. The angles which it makes with the sheer and level lines indicate the bevellings which the timber will have in horizontal sections at those heights. If they are found too great, it must be concluded that the heel of the timber cannot be brought upon s . To obtain the vertical trace of this plane, observe first, that it must pass through i' , and that it must meet the axis, $L T$, at the same distance from the middle line as B does, (i.e.) $L k$ must be equal to $L h$. These two points are, however, too close together to define the line B' accurately; observe, therefore, that if a horizontal line, $C O$, were drawn from the point c' , in the plane of which B is the trace, its horizontal projection would be $c o$, and its vertical projection $c' o'$. But the point O must be in the line of intersection of the plane of the side of the timber and the plane of projection, in other words, the vertical trace

we seek must pass through O , or, which is the same thing since O is in the plane of projection, through o' , its vertical projection. If, therefore, we join $k' o'$, we have the line B' , the vertical trace required. It will be seen that the plane $B B'$ cuts the planes I., II., III., in straight level lines starting from n' , k' , and p' respectively. That through k' is coincident with the trace B , and the others are parallel to it. The horizontal projections of these lines will evidently be $n r$, $k h$, and $l p q$. The lowest of these lines, $p q$, lies in the same plane as the level line III., and since it also lies in the plane $B B'$, the point q in which it meets the level line, is in their intersection, and is therefore a point in the required edge of the timber. Similarly, h and r are points in this edge; d and c we already know to be so. Join d, r, h , and q by a curve, and we have the horizontal projection of the moulding edge of the timber. So also by means of the plane $A A'$, we obtain $b v$, the moulding edge of the outer timber, as we might also that of the inner timber by means of the plane $O O'$. To find points in the vertical plane corresponding to these, we have only to set off corresponding breadths on the several lines, by which we obtain as the vertical projection of the moulding edge $c', d', e', k' q'$. The points n and n' , corresponding in like manner, give the ending of the edge at the side of the cant.

To discover the true shape, the plane containing the moulding edge must be thrown down upon the vertical plane of projection about the vertical trace—in this case therefore, about B' . During the revolution the points of which c', d', e', k', n' , and q' are the projections, will describe circles at right angles to the line B' , and will fall in lines drawn through these points at right angles to B' . Consider now for a moment the level plane III. Both P and Q , of which p' and q' are projections, lie in this plane, and their actual distance from each other is $p q$, seen in the half-breadth. In the revolution, P being in the axis, does not move; the point Q will therefore be found at a distance from the axis, or from p' , equal to $p q$. Take then, in a pair of compasses, the length $p q$, and sweep a circle from p' , cutting the square line through q' in Q , and Q will be a point in the moulding edge. Set off similarly $k' H$, equal to $k h$; $n' R$ (R is omitted in the figure) equal to $n r$; $m' D$ equal to $m d$; and $o' C$ equal to $o c$; join these points, and we have the true shape of the timber. In setting off the distances for the knuckle and roughtree, it must be observed that a line drawn from (d, d') in the plane of the moulding edge and parallel to the horizontal plane, will meet the vertical trace of the plane in m' , below the curve. And that similarly a horizontal line drawn from c' in the plane of the moulding edge will meet the plane of projection in o' . It is therefore m' and o' , and not points in the curved lines themselves, which correspond to m and o in the half-breadth, and from which the distances must be set off.

BREECH-LOADING SMALL ARMS.

CAPTAIN NORTON writes:—"To the Editors of the MECHANICS' MAGAZINE. Gentlemen,—I am happy to be enabled to inform you that breech-loading sporting guns may be made available as military arms in case of emergency, simply by using gossamer cartridges, and a close-fitting spherical bullet enclosed in a thin greased patch of cotton net; this I successfully proved this day at Mr. Riley's shooting-gallery, 315 Oxford-street, W. The young man attending there fired three blank cartridges in succession without failure; the felt wad, forming the head of the cartridge, carries the unconsumed portion of the thin tough paper and cotton net clean out of the barrel at every discharge. The American civilians did good service with their smooth-bore sporting guns at the battle of Bunker's Hill. By following the above-described plan of using sporting guns, England could instantly command the willing services of a million ready-trained and well-armed guerillas of native growth, and racy of the soil. Your obedient servant, J. NORTON. Rosherville, 23rd August."

It is expected that the *Mercy*, 40, screw frigate, at Spithead, will shortly receive several of Sir W. Armstrong's guns, in addition to her present armament.

THE HYDRAULIC LIFT AT THE VICTORIA DOCKS.

THE HYDRAULIC LIFT AT THE VICTORIA DOCKS.

Invented by Mr. EDWIN CLARK.

ON Wednesday, the 27th of July, many who are interested in the progress of science had the pleasure of seeing in successful operation at the Victoria Docks Mr. Edwin Clark's method of ship-lifting, which appears likely to supersede the graving dock for many purposes. Mr. Clark's apparatus consists of a series of thirty-two upright hydraulic rams, of ten inches in diameter, placed in a waterway in two lines of sixteen each, far enough apart to admit of a ship of any burden passing between. Each ram is fitted with a cross-head of wrought-iron, and the crossheads are supplied with long straps, to the lower end of which are connected girders extending across from row to row. These girders, when the rams are down, are of course at the bottom of the water. The pontoon, on which the ship is raised, is formed of wrought-iron plate, strongly ribbed, the length and depth of which varies according to the size of the ship it is intended to lift. This pontoon is open at the top, and is of sufficient buoyancy, when empty, to support a vessel of very large tonnage. It is fitted with screw valves for admitting the water, so that in a very short time, when placed in position, it can be lowered down upon the cross girders. The rams are fed by a 50 lb. engine, which is fitted with twelve hydraulic pumps, 1½ in. diameter, and 2 ft. stroke, working at 18 strokes per minute, and the pipes from these pumps, before branching off to the rams, communicate with a series of valves arranged in a place built for that purpose close to the lift. By means of excentrics, which close the valves, any one of the rams can be disconnected at will from the supply, so that should one of the pipes burst, no danger can accrue to the ship, and the lifting process can be completed without delay.

At half-past 1 o'clock on Wednesday, the 27th, the pontoon being placed in position upon the girders, it was first filled and then lowered to the bottom of the water. After this the Jason, a ship of about 1,000 tons burden, was warped in, and having been fixed in position by means of ten sliding blocks, which were pulled into contact with the sides and bottom by means of chains brought above the water line, the engine was set to work,

and the whole mass rose gradually out of the water at a speed of one foot in three minutes. As the pontoon came above the surface, it relieved itself of the water it contained, and the valves being then closed, the buoyancy of the saucer itself supported the ship in a perfectly steady and satisfactory manner. The whole operation, from the beginning to the end, extended over the space of 1½ hours, and the dead weight lifted, including the pontoon, was altogether above 1,600 tons. There are four pontoons constructed, and others in course of construction, which when raised in this manner, and floated, are to be towed with their burden into shallow bricked recesses provided for that purpose, so that the hydraulic power can be continuously applied for raising purposes. During an entertainment which followed the experiment, or rather the operation, Mr. Edwin Clark laid before his audience a clear and concise description of his invention, and the obstacles he had had to contend with in bringing it to its present state of perfection.

The engraving No. 1 shows a cross section of the lift, with a ship in the act of being raised. *A A* are two of the columns in which the rams are placed; *B* shows one of the cross girders; *C*, the end of the pontoon; *D D*, two of the sliding blocks for steadying the ship, and *E E* are two double purchase crabs for raising weights, and lifting the rams when required. These can be run about anywhere upon the top platforms, and are very useful adjuncts.

Engraving No. 2 is a section, in detail, of one of the columns, showing the ram, which is lettered *A*, the cross-head *B*, the side rods *C C*, and the cap plate *D*. It will be noticed that the hydraulic cylinder containing the ram rests upon a block of concrete, which fills up the inside of the column to the required height.

It will be needless for us to say much more upon the subject of Mr. Clark's invention. Its superiority over the old graving dock for many purposes is sufficiently manifest. Instead of a vast outlay upon excavations, masonry, and elaborate machinery in each instance, one hydraulic lift will do the work of any number of graving docks; and the only expense, beyond the first outlay, is providing an adequate number of pontoons for the work, and water space of any kind beyond three feet deep for floating them in.

A NEW MARINE LIGHT.

COMMODORE the Hon. James R. Drummond and the officers of Her Majesty's Dockyard, Woolwich, were on Saturday night last engaged in testing a newly-discovered light, denominated "the photophore," intended for lighthouses, and all the purposes of lights at sea. The paddle-wheel steam-vessel Bustler, in charge of Mr. Thomas, master - commanding the Fisgard, having on board Mr. Ferdinand Silas, a native of Holland (the inventor of the photophore), left the dockyard jetty at half-past 8 o'clock, and, having hoisted one of the new lights at the mast-head, proceeded slowly down the river for a short distance, while a number of the instruments passed along the banks were lighted up, the pale red glare of which was easily distinguished from that of all other lights, and was also pronounced to be more brilliant. Commodore Drummond remaining stationed on the jetty directed a course of signals by the constant lighting and extinguishing of the photophore, which was similarly replied to by the inventor on board the Bustler. One of the instruments attached to a line was thrown into the water without being previously lighted, and on rising to the surface it shot forth a phosphoric blaze, which, according to the inventor's statement, would keep alive for 10 or 12 hours.

THE STEERING OF SCREW STEAM-SHIPS.

THE difficulty of steering long ships has always been a great impediment to the lengthening of crew steam-ships, particularly in the case of war vessels, which should be capable of performing rapid evolutions. During some recent experiments on board his steam-yacht, the Dragon-fly, Mr. Joseph Maudslay discovered a fact which appears to us to have a very important bearing upon this subject. The screw-propeller of the Dragon-fly is fitted with feathering-blades, which are capable of having their pitch varied with the utmost ease from the deck, either when the screw is at rest or when it is revolving at any speed. The remarkable fact which Mr. Maudslay has observed is, that when both blades are set in the line of the keel—or, in other words, in the longi-

tudinal plane passing through the centre of the ship—and the screw is set revolving, the vessel is turned round very rapidly. If, when the vessel is going at a considerable speed, in the usual way, the blades are rapidly brought into the position before stated, she also turns very quickly.

We content ourselves, for the present, with placing this fact on record, only remarking that, while it is not difficult to see how it is to be accounted for, it is impossible not to view it as very important.

We subjoin an engraving of Mr. Maudslay's feathering screw (which was published in our Magazine for 1856) in order that the nature of the feathering propeller may be apparent to our readers. A glance at the several figures will make its construction evident to practical men.

FREE DRINKING FOUNTAINS.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—In an article on free drinking fountains in your excellent Magazine of the 19th instant, you describe certain arrangements which it is stated the Metropolitan Free Drinking Fountains Association has adopted for the filtration of water at their fountains. As this account is not altogether correct, we beg to be allowed to state that the only means hitherto used for the filtration of water at the fountains of the Association, as well as at various others in the metropolis, are the filters of the Moulded Carbon Company, designed and supplied by us. The annexed figure will probably afford a better explanation of the arrangement adopted, than that which is conveyed by your representation.

A is an iron cistern containing a hollow cylinder of moulded carbon B, which is suspended to the lid by a nut F, through which the pipe E is passed into the carbon. The unfiltered water enters by the pipe C, which is perforated on its underside within the cistern, and made to surround the cylinder; by this means the water flows continually over the whole surface of the carbon, and prevents the deposition of insoluble matter upon it, which is carried down to the bottom of the cistern, from where it may occasionally be drawn, and the whole cleaned out by opening the tap G. D, tap to regulate the supply. E E are union joints, by which the apparatus can be fixed

FIG 1.

or removed in a few minutes. This filter may also be conveniently attached to the main or supply pipe in dwellings.

As the names of others have been introduced in your article, by which it will be understood that the filtering medium has been prepared and supplied by them, we trust you will favour us by giving insertion to this letter in your next number.

HARRISON AND CO.

62 Fleet Street.

ADMIRALTY EXPERIMENTS ON IRON-SIDED SHIPS.

A SERIES of experimental trials have been carried on during the past fortnight at Portsmouth, with a view of ascertaining the amount of resistance offered by iron and steel plates of various manufactures when opposed to heavy ordnance at a short range. The trials are understood to have reference to the future coating of the steam ram now in progress of construction. The practice has been carried on from the Stork gunboat, tender to Her Majesty's ship Excellent, gunnery ship in Portsmouth harbour, both from a 32-pounder and a 95 cwt. gun, the latter throwing a solid 68lb. shot, with 16lb. charge of powder; the distance of range 200 yards. At this distance the results of the experiments have demonstrated in the clearest possible manner that no iron or steel

plate that has yet been manufactured can withstand the solid shot from the 95 cwt. gun at a short range. The first shot would not penetrate through the iron plate, but it would fracture it, and on three or four striking the plate in the same place, or in the immediate neighbourhood, it would be smashed to pieces. As the results of the trial affected the steel plates it proved that a steel-clothed ship could be far more easily destroyed than a wooden-sided one, and that on the smashing-in of one of the steel-plates the destruction of life on the armed ship's decks, supposing the broken plate to be driven through the ship's side, would be something dreadful to contemplate, from the spread of the splintered material. At from 600 to 800 yards iron-clothed ships would be in comparative safety from the effects of an enemy's broadside, but it must be borne in mind that the effects of concentrated firing have yet to be ascertained on the sides of an iron-clothed ship, and account also must be taken of the damage the woodwork forming the inner sides of such a ship would receive from the driving-in of the broken plates; and which, as far as the present experiments have illustrated, would appear to prove that an iron or steel-clad ship, on receiving a concentrated broadside from a frigate, armed in a similar manner to the *Mersey*, and struck near her waterline, must sink then and there, with her armour on her back.—*Times*.

Literature.

The Navies of the World; their Present State and Future Capabilities. By HANS BUSK, M.A., of Trinity College, Cambridge. With Illustrations. London: Routledge, Warne, and Routledge, Faringdon-street. 1869.

WHEN report on report and parliamentary return on parliamentary return, all abounding in information relating to the navy, came pouring forth at the commencement of the present year, we felt perfectly sure that some one or other would hash them up into the form of a volume, with a loud-sounding title, and have it advertised from one end of the world to the other. As Mr. Hans Busk, Master of Arts, Barrister-at-Law, Lieutenant of the Victoria Volunteer Rifles, author of "The Rifle, and How to Use It," &c., is rather fond of getting up books apparently, there seems to us no reason why he should not have been the man to undertake the business; and Mr. Busk himself appears to have thought the same. We are glad he has done so, because, he failing, the undertaking might have fallen into the hands of some idle person, who would have performed it far less satisfactorily than he. Considering who Mr. Busk is, and how very little he could be expected to know of the world's navies, he has really done his work astonishingly well. In order to acquaint our readers with the spirited manner in which he has gone about it, we quote the following extract from the author's preface. In perusing it, let no reader object to the frank testimony which Mr. Busk bears to the zeal and the successes of Mr. Busk. A little fluent freedom of that kind on the part of an author will not do us any harm—unless it should become common! Mr. Busk says:—

"An earnest desire to obtain authentic intelligence on these matters stimulated the author, during the latter part of the past year, to visit the several French naval stations, at some of which he encountered a variety of obstacles, although he finally succeeded in his object beyond his most sanguine expectations. In the prosecution of his inquiries, the writer travelled several thousand miles in France, associated and conversed with people of various grades and professions, as well at the military and naval stations, arsenals, and seaports, as in the large cities and manufac-

turing towns, and in the rural districts; with officers of both services, landed proprietors, merchants, lawyers, and also with peasants and artisans, sailors and fishermen. He had thus the best opportunities of acquiring information, and of learning the feelings entertained towards this country by a great number of Frenchmen. Although he cannot but admit that he experienced on no occasion any lack of personal courtesy, it must still be allowed that if some of the opinions he heard were reproduced at home, in the precise terms in which they were originally expressed, our national vanity would scarcely feel flattered by the sentiments towards us so frankly avowed. With the view, moreover, of fully ascertaining the real capabilities and present condition of the navy and arsenals of France, he passed some time at Toulon, at Rochefort, at Lorient, at Brest, and at Cherbourg, carefully investigating all that had been done of late years at those several ports, inspecting the works in progress at each. He was, besides, fortunate enough to obtain access to important and unpublished official documents, so as to check the accuracy of oral information. By this means he was enabled to ascertain precisely the present strength of the French marine, the age of every ship, the port at which she was built, the number of her guns, and in the case of steamers the horse-power of each. This information, collected as it is from trustworthy sources, cannot but be deemed, at the present juncture of considerable value; and if the jealous care of the French Government, in withholding such knowledge, be taken into account, and consequently the extreme difficulty of procuring statistical facts of the kind, in a country where not only no official navy list is published, but where no catalogue of the sort is allowed to be publicly circulated under any pretence, some estimate may be formed of the toil necessary to succeed in an enterprise apparently so hopeless as the one undertaken by the author. Patient perseverance, however, overcame all difficulties, and the result of his labours will be found incorporated in the following pages. The summary there furnished will certainly afford matter for reflection. That very numerous class of our countrymen who have been accustomed, from the many disastrous defeats sustained at sea by France, during former wars, to regard her maritime resources as immeasurably inferior to our own, will learn with some astonishment that, chiefly owing to the energetic exercise of her indomitable will, she has been for some time past steadily gathering together her giant strength, and could at a very brief notice, if need were, equip for sea a fleet of more than four hundred vessels, of which nearly threescore would be ships of the line! At the same time, the whole available strength of England's bulwarks, numerically reckoned, cannot be considered very materially to exceed that of France, and this is especially the case as regards effective line-of-battle ships and frigates. One of the author's chief objects, also, has been to collect authentic information on the present condition and future prospects of our own navy; in detailing which, in its proper place, he has ventured briefly to introduce such views and suggestions for its improvement as may have occurred to himself, or have been derived from a careful examination of the opinions expressed by experienced naval men and other competent authorities. A slight sketch of the actual state of the navies of other maritime powers—as Russia, the United States, Holland, Austria, Denmark, Sweden, &c.—has also been appended, so as to present, in a compact form, a comparative view of the existing 'navies of the world.' Besides the above topics, the author has thought it essential to a full elucidation of the subject to devote separate chapters to the consideration of other matters intimately connected with the whole question; such as the application of steam to ships-of-war, and especially the important introduction of the screw; naval gunnery, as based upon the vastly improved ordnance now in use, as well as the

altered character of naval evolutions rendered necessary by these changes. He has, moreover, felt called upon to express his opinions upon the apparent inefficiency of the old Admiralty Board in coping with the urgent requirements of the present critical juncture. And, though last, not least in importance, our coast and land defences will be found discussed, if not with adequate ability, at least in a sincere and earnest spirit. In connexion with this latter topic, the author has ventured to call public attention to the great advantage of training a portion of the civilian population to the use of arms, through the medium of volunteer associations, organised under the sanction of Government, so as to be available on an emergency as a valuable reserve."

Although we are not disposed to treat Mr. Busk's volume with the gravity which a profound and well-studied work on the "Navies of the World" would deserve, we would have it understood that the author has not bestowed his labours grudgingly upon it. He has amassed an unexampled amount of information relative to the French navies and naval ports, and to this he has added useful descriptions of other foreign navies. His detailed lists of our own navy are also very copious and complete, and, so far as we have observed, very accurate also. The volume also comprises a reprint of the "Conversations-Lexicon" article on the English and French navies, together with a spirited review of the same.

But we cannot, in justice to our numerous naval readers, fail to say that the volume is not without serious errors—errors into which none but a purely amateur writer could have fallen. For example, in the detailed statement of the strength of our own navy, we are gravely informed, in a special note, that our three-deck screw ships draw from 35 to 36 feet of water! And, that there may be no doubt as to the deliberation with which these figures are given, we are further told that twenty-two of the two-deck screw ships draw about 34 feet; and the rest about 32 feet. Now, no naval man need be told that these are most absurd statements. The ship which draws more water than any other in our navy is the *Duke of Wellington*, and her draught is about 27 ft. 6 in. aft., and 25 ft. 6 in. forward; her mean draught being, therefore, 26 ft. 6 in.—nearly 10 feet less than Mr. Busk says! In making all due allowances for Mr. Busk's circumstances, as the author of a work on a subject lying so very remote from his professional calling, we really are still astonished to find him falling into such an error as this. Ships drawing 36 feet of water may, perhaps, be built by coming generations, but if they should be, they will certainly find entrance into very few of our ports.

There are other portions of this volume which have but little interest for us, but which may be very useful nevertheless to many others, especially to those who are not readers of the *MECHANICS MAGAZINE*. We meet with a good deal that has appeared from time to time, and in various forms, in our columns; such as descriptions of the Armstrong gun, the Whitworth gun, Captain Norton's and Captain Blakely's inventions, Mr. Macintosh's system of warfare, and so forth. We also, we regret to say, meet with not a little loose writing about "Admiralty jobbery," the "shortcomings of that department," &c. We do not believe that such writing can do any good. We have already plenty of men who are fluent enough in quoting epithets; we want no more of them; what we do want are men who can take up facts

ith fairness and impartiality, weigh and balance sem with intelligence, and then give us the result of their deliberations calmly, nothing extenuating nor setting down aught in malice.

On the whole Mr. Busk's book may be taken as useful and timely compilation, and while no one must believe all that it says, many may read it with profit.

THE STRENGTH OF GLASS GLOBES AND CYLINDERS.

By W. FAIRBAIRN and T. TATE.

THE following communication was read to the Royal Society:—"On the resistance of glass globes and cylinders to collapse from external pressure, and on the tensile and compressive strength of various kinds of glass." By William Fairbairn, Esq., C.E., F.R.S., and T. Tate, Esq., F.R.A.S. Received May 3, 1859. We have since obtained the following official abstract of the paper:—

The researches contained in this paper are in continuance of those upon the resistance of wrought-iron tubes to collapse, which have been published in the "Philosophical Transactions" for 1858. The results arrived at in those experiments were so important as to suggest further inquiry under the same conditions of rupture with other materials; and glass was selected, not only as differing widely in its physical properties from wrought-iron, and hence well fitted to extend our knowledge of the laws of collapse, but because our acquaintance with its strength in the various forms in which it is employed in the arts and in scientific research is very limited. To arrive at satisfactory conclusions, the experiments on this material were extended so as to embrace the direct tenacity, the resistance to compression, and the resistance to bursting, as well as the resistance to collapse.

The glass experimented upon was of three kinds:—

	Specific gravity.
Best flint-glass	3.0782
Common green glass	2.5284
Extra white crown-glass	2.4504

TENACITY OF GLASS.

For reasons detailed by the authors, the experiments upon the direct tenacity of glass made by tearing specimens asunder are less satisfactory than those in the rest of the paper; and it is argued that more reliance is to be placed upon the tenacity deduced from the experiments on the resistance of globes to bursting in which water-pressure was employed, than upon the tenacity obtained directly by tearing specimens asunder. The results obtained by the latter method give the following mean results:—

	Tenacity per square inch in pounds.
Flint-glass	2413
Green glass	2896
Crown-glass	2346

RESISTANCE OF GLASS TO CRUSHING.

The experiments in this section were made upon small cylinders and cubes of glass crushed between parallel steel surfaces by means of a lever. The cylinders were cut of the required length from rods drawn to the required diameter, when molten,

and then annealed, in this way retaining the exterior and first cooled skin of glass. The cubes were cut from much larger portions, and were in consequence probably in a less perfect condition as regards annealing. Hence, as might have been anticipated the results upon the two classes of specimens, although consistent in each case, differ widely from one another.

The mean compressive resistance of the cylinders, varying in height from 1 to 2 inches, and about 0.75 inch in diameter, is giving on the following table:—

Description of glass.	Height of cylinder in inches.	Mean crushing weight per sq. in.		Mean crushing weight per sq. in.	
		in lbs.	in tons.	in lbs.	in tons.
Flint-glass	1	29,168	13.021	27,582	12.313
	1.5	20,775	9.274		
	2.0	32,803	14.644		
Green glass	1	22,583	10.081	31,876	14.227
	1.5	35,029	15.628		
	2.0	38,105	16.971		
Crown-glass	1	23,181	10.348	31,003	13.840
	1.5	38,825	17.332		
	2.0				

The specimens were crushed almost to powder by the violence of the concussion; it appeared, however, that the fracture occurred in vertical planes, splitting up the specimen in all directions. Cracks were noticed to form some time before the specimen finally gave way; then these rapidly increased in number, splitting the glass into innumerable prisms, which finally bent or broke, and the specimen was destroyed.

The following table gives the results of the experiments upon the cut cubes of glass:—

	Mean resistance to crushing. in pounds.	in tons.
Flint-glass	13,130	6.861
Green glass	20,206	9.010
Crown-glass	21,867	9.762

Hence, comparing the results on cylinders with those on cubes, we find a mean superiority in the former case in the ratio of 1.6:1, due to the more perfect annealing of the glass.

ON THE RESISTANCE OF GLASS GLOBES TO INTERNAL PRESSURE.

In these experiments the tenacity of glass is obtained by a method free from the objections to that before detailed. Glass globes, easily obtained of the requisite sizes, in a nearly spherical form, were subjected to an internal pressure obtained by means of a hydraulic pump, uniformly and steadily increased till the globe gave way. The lines of fracture radiated in every direction from the weakest part, passing round the globe as meridians of longitude and splitting it up into thin bands, varying from 1/16th to 1/4th of an inch in breadth.

The following table gives the results of the experiments on the resistance of glass globes to internal pressure:—

Description of glass.	Diameters.	Thickness.	Bursting pressure per sq. in.	
			Inches.	Pounds.
Flint-glass.....	4.0 by 3.08	0.024		84
	4.0 by 3.98	0.025		93

The formula which expresses the relation of the bursting pressure to the thickness and diameter of the globe, is:—

$$P = \frac{aT}{A}$$

where a = the longitudinal sectional area of the material in square inches, that is, in the line of

rupture or line of minimum strength; A = the longitudinal sectional area of the globe in square inches; and T = the tenacity of the glass in pounds per square inch. Hence, from the above experiments we deduce:—

Pounds.
 $T = 4200$ for flint-glass,
 $= 4800$ for green glass,
 $= 6000$ for crown-glass,

5000 = mean tenacity of glass.

Here the mean tenacity is nearly twice that obtained in the experiments upon thick bars; a result which, perhaps, corresponds with the difference between the crushing strength of cylinders and cubes, and is largely attributable to the condition of annealing.

ON THE RESISTANCE OF GLASS GLOBES AND CYLINDERS TO AN EXTERNAL PRESSURE.

The manner of conducting these experiments did not differ in any essential detail from that pursued in the experiments upon wrought iron. The globes and cylinders, after having been hermetically sealed in the blowpipe flame, were fixed in a wrought-iron boiler communicating with a hydraulic pump. In this position an increasing pressure was applied until the globes broke, the amount of pressure at the time being noted by means of a Schäffer pressure-gauge. During the collapse the globes were reduced to the smallest fragments, so that no indication of the direction of the primary lines of fracture could be discovered.

The following table contains a summary of the results on globes subjected to an external pressure:—

Description of glass.	Diameters.	Thickness.	Collapsing pressure per sq. in.	
			Inches.	Pounds.
Flint-glass ...	5.05 by 4.76	0.014		292
	5.08 by 4.7	0.018		410
	4.95 by 4.72	0.022		470
	5.6	0.020		472
	8.22 by 7.45	0.010		35
	8.2 by 7.2	0.012		42
	8.2 by 7.4	0.015		60
	4.0 by 3.98	0.024		(900*)
	4.0	0.025		(900*)
	6.0	0.039		(1000*)
Green Glass	5.0 by 5.02	0.0125		212

The following table contains a similar summary of the results upon cylindrical vessels:—

Description of glass.	Diam.	Length.	Thickness.	Collapsing pressure per sq. in.	
				Inches.	Pounds.
Flint-glass...	3.09	14.0	0.024		85
	3.03	14.0	0.032		103
	3.25	14.0	0.042		175
	4.05	7.0	0.031		202
	4.05	7.0	0.046		380
	4.06	13.8	0.043		180
	4.02	13.8	0.064		297
	3.98	14.0	0.076		382
	4.05	7.0	0.079		(500+)

The paper includes an investigation of the laws of collapse in these results, and the following general formulæ are obtained:—

$$\text{For glass globes } \dots P = 28,300,000 \times \frac{k^{1.4}}{D^{1.4}}$$

$$\text{For glass cylinders } \dots P = 710,000 \times \frac{k^{1.4}}{D.L}$$

where P = the collapsing pressure in pounds per square inch; k = thickness in inches; D and L = diameter and length respectively in inches.

These are the general formulæ for glass vessels subjected to an external pressure, and the latter is precisely similar to that found for sheet-iron cylinders.

TRANSVERSE STRENGTH OF GLASS.

The authors derive the general formula

$$W = 8140 \times \frac{K.D}{l}$$

where W = breaking weight in pounds, K = area of

* These globes remained unbroken.
 † Remained unbroken.

transverse section, D =depth of section, l =length between supports; to express the transverse strength of a rectangular bar of glass supported at the ends and loaded in the middle.

Our Weekly Gossip.

Charles Barry sends us the following letter, in once to that of Mr. Loseby which appeared a fortnight since in this Magazine, and in the Society of Arts' Journal the succeeding week:—

"TO THE EDITORS OF THE MECHANICS' MAGAZINE."

"Gentlemen,—My attention has been called to a letter in the last number of the *Journal of the Society of Arts*, from Mr. Loseby, respecting the Westminster clock, in which he alludes to a statement recently made in the House of Commons by Mr. Fitzroy respecting the minute hands made by my authority, the weight of each of which he reported to be above 3 cwt.

"That statement was made, I find, upon the authority of Mr. Denison alone, and, as it has already misled Mr. Loseby, and possibly the public also, I think it right to put you in possession of the facts of the case.

"These hands, which are now condemned by Mr. Denison, were prepared under his own control; one of them was submitted to him as a specimen before the remaining three were made, and met with his cordial approval: the others were made by his orders, in strict accordance with the specimen which he had approved; and he fixed the whole of them when finished, and made himself responsible for the cost of so doing. The weight of each hand, exclusive of the external counterpoise, is 1 cwt. and 25 lbs.

"It is obvious, therefore, that Mr. Denison, and he alone, is as fully responsible for those hands as he is for all the other going parts of the clock.

"I am, Sir, yours faithfully,

"CHARLES BARRY."

"Old Palace-yard, Aug. 23."

A correspondent—an experienced naval officer—politely favours us with the following remarks upon the Russian frigate General Admiral, now lying at Spithead:—"I have just come on shore from a visit to the Russian frigate General Admiral, and I will give you some rough notes of my observations. She is certainly a very fine vessel, built quite on the American plan, with fine lines forward and aft, much spring, no head knee, and altogether resembling a large cotton ship with guns in her. We were certainly much disappointed with her main deck: the guns are very close together, ports only seven feet from each other, and the beam of the ship not in proportion to her length. The ship had been so recently commissioned that it could not be expected that she should be in perfect order; but still she was very fair, and every endeavour was evidently being made to fit her well up. The guns were being polished, and the crew were otherwise actively engaged in bringing her into order. She has guns on her gunways, and the objection which has hitherto existed towards this by the want of room has been met by stowing the boom on galleys, leaving the whole deck clear. A very large bridge nearly covers the quarter deck, under which is a cabin, which we understood was the captain's. The armament consists of thirty 7½ inch guns and two 5 inch guns on main deck, and twenty-eight 8 inch and two 16½ inch on upper deck, making in all sixty-two guns mounted, although she is pierced for seventy-two guns. The carriages of the broadside guns are on the French plan—no after trucks—each carriage being provided with a roller handspike for training, &c. The knees of the ship are wood, with a thin broad iron plate on the outside. Large bins extend the whole length of the lower deck for the men's clothes. We understood that she has not all her coals on board; the midship main deck port is 12 ft. 2 in. out of the water, which, of course, is a great height. One of the officers informed us that she was 325 feet between perpendiculars. The main deck is 7 ft. 6 in. high between the beams; the engines were stated to be 800-horse, and the greatest speed they have got out of her 12½. Just after we had left, the Mersey ranged up close alongside; and the comparative sizes, &c., of the two frigates were admirably seen. The impression left on our minds was that the Mersey was much the finest frigate of the two. Yet I must repeat that His Imperial Majesty's ship General Admiral is unquestionably a fine frigate, and suggests the necessity of our keeping a vigorous eye upon a country which is evidently endeavouring to excel in this important

description of ship-of-war." In a former number of the MECHANICS' MAGAZINE the following memoranda respecting this vessel (which was built at the yard of Mr. Webb, of New York), was copied from the *Scientific American*:—"Her model is what is called the long flat floor, full bilge, sharp end, round stern, no poop or cut-water, and short fore-castle deck. She is expected to attain a speed of fourteen knots under sail, and her draft of water will not exceed 25 feet. Her dimensions are:—Length on spar deck, 307 feet; breadth, 55 feet; length over all, about 325 feet; depth to spar deck, 34 feet. She is pierced with 44 side ports and two stern ports on the lower deck, and 30 side ports and 4 large ports forward, and 4 large ports on the spar deck. Her armament will consist of 40 shell guns of large calibre on the gun deck, and 20 long guns and 2 pivot guns of largest size on her spar deck. She is built of white oak, and will be propelled by two direct horizontal engines, now building at the Novelty Works, this city, each cylinder of which will be 84 inches in diameter, and 3 feet 6 inches stroke, with a nominal power of 2,000. The propeller is 10½ feet in diameter, and is one of Griffith's patent."

"Sir William Armstrong, Superintendent of the Rifled Ordnance Department at Woolwich, has succeeded," we are told by the *Times* correspondent, "in accomplishing the method of rifling the whole or any requisite number of the guns employed in the service which present a surface at the bore fit to receive and maintain the grooves, and which possess a body of sufficient tensile strength to resist the explosive power required to expel, with safety, the heavy shot now in use. Some experiments have been carried out at Shoeburyness in the most successful manner with some of the guns which have undergone the metamorphosis, or transformation from the smooth to the rifled bore, hitherto considered impracticable. The first gun submitted to trial was an 80-pounder on Sir William's original plan; the second, an ordinary 32-pounder service gun rifled on a plan of Sir William Armstrong's, adapted for elongated cast-iron shot or shell. They were transported from the department in Woolwich Arsenal without preliminary proof or test, as the most implicit confidence is placed in the judgment of Sir William Armstrong, and were fired over a range of 3,400 yards. The result exceeded the general anticipation. The target was six feet square, into which every shot—namely, six rounds from each gun—penetrated with terrific and certain aim (*sic*). The energy and diligence displayed in the present restricted limits of the establishment present ample evidence of Sir W. Armstrong's stipulation to furnish 100 guns for service during the present year being fully and faithfully performed. The whole of that number are already in form, and will be completed and delivered under ordinary circumstances long before the prescribed period." We quote this not very lucid statement that it may be taken for what it is worth; but we warn our readers against attaching too great importance to it. If the writer is not careful he will be making us believe that a common gun rifled is of more value than the costly and delicate, though famous, Armstrong gun.

"Sidmouth, August 24, 1859.—Gentlemen,—I feel much indebted to Mr. Hearder for the very kind manner in which he replied to my question with respect to the magnetic coil and battery, which appeared to me very much to the purpose,—that by adding another pair of plates to the battery and connecting similar poles you simply double the surface. I have tried the experiment in the manner Mr. Hearder proposed, viz., dividing my battery of twelve into two of six, and connect their similar poles; they give about the same result as before, that is, with the eleven in series and one extra. I find when operating with the two sizes if I take an extra pair of plates and connect similar poles the effect is again doubled or trebled, and I think it cannot be attributed to extra surface, as proposed by Mr. Hearder, inasmuch as if I only dip the tip of the plates in, it has all the effect the same as immersing the whole. I believe a thimble battery would be quite sufficient for the extra pair. If Mr. Hearder would try the experiment and give the result through the MECHANICS' MAGAZINE, he will confer a great favour on yours very truly, S. CHICK."

On Tuesday and Wednesday the Great Eastern was densely crowded with visitors, the grand saloon, which had been closed in consequence of damage done to the furniture by some ill-disposed persons, being re-opened for inspection on those days only, and the price of admission being raised to 5s. It is stated that no public intimation will be given as to the exact time of her departure from the Thames, in order to avoid the inconvenience which might arise from a crowded state of the river.

NOTICES.

M., of Preston.—Do not be angry with us: answering questions is really no part of our business, and if it were it would be a part to which we could not afford to devote time. Nine out of ten of the requests made to us in this respect are either absurd or inconsiderate, and we therefore attach but little importance to them. You, being a sensible man and a man of business, we hope, would, we dare say, become as glibly as ourselves were you in our position. The screw propeller to which you refer is Mr. Joseph Maudslay's patent feathering screw, and the yacht in question is the Dragon Fly. The screw was described and illustrated in the MECHANICS' MAGAZINE, No. 1724, for Aug. 23, 1856; it has not, we think, been altered from the form there described. (See p. 137.) We cannot undertake to prescribe for the pitch of your new screw.

The MECHANICS' MAGAZINE will be sent free by post to all subscribers of £1 ls. 8d., annually, payable in advance. Post Office Orders to be made payable to R. A. Brooman, at the Post Office, Fleet Street, London, E.C.

TO ADVERTISERS.

All Advertisements occupying less than half-a-column are charged at the rate of 5d. per line for any number of insertions less than 13; for 13 insertions, 4d. per line; and for 52 insertions, 3d. per line.

Each line consists of 10 words, the first line counting as two. Wood-cuts are charged at the same rate as type for the space occupied.

Special Arrangements for larger or Serial Advertisements To ensure insertion, Advertisements must reach the Office by 5 o'clock on Thursday evening each week. None can be received after that time for the ensuing number.

THE demand for Mr. E. J. REED'S paper—

ON THE MODIFICATIONS WHICH THE SHIPS OF THE ROYAL NAVY HAVE UNDERGONE DURING THE PRESENT CENTURY, IN RESPECT OF DIMENSIONS, FORM, MEANS OF PROPULSION, AND POWER OF ATTACK AND DEFENCE," has been so great that the *Journal of the Society of Arts*, the MECHANICS' MAGAZINE, and all other Scientific Journals in which it appeared in December last, are now out of print. The demand still continuing, it has been deemed desirable to reprint it in a separate form. An 8vo. edition of it, in large type, and on fine paper, has, therefore, been prepared, and may now be had at the Office of this Magazine, price 1s.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgement:—

STEAM ENGINES, &c., 65, 70, 90, 97, 98, 108, 120.
BOILERS AND THEIR FURNACES, &c., 69, 86, 89.
ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 81, 112.
SHIPS AND BOATS, including their fittings, 66, 92, 107.
CULTIVATION OF THE SOIL, including agricultural and horticultural implements and machines, 110.
FOOD AND BEVERAGES, including apparatus for preparing food for men and animals. None.
FIBROUS FABRICS, including machinery for treating fibres—pulp, paper, &c., 49, 52, 53, 54, 59, 78, 88, 105, 118.
BUILDINGS AND BUILDING MATERIALS, including sewers, drain-pipes, brick and tile machines, &c., 99.
LIGHTING, HEATING, AND VENTILATING, 55, 77.
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 57, 69, 74, 76, 83, 90, 93, 109, 111, 116, 117.
METALS, including apparatus for their manufacture, 100, 101.
CHEMISTRY AND PHOTOGRAPHY, 51, 67.
ELECTRICAL APPARATUS, 56, 84, 87, 96, 119.
WARFARE, 114.
LETTER PRESS PRINTING &c. None.
MISCELLANEOUS, 50, 58, 61, 62, 63, 64, 68, 71, 72, 73, 75, 79, 80, 82, 85, 87, 94, 95, 102, 103, 104, 106, 113, 115.

49. J. H. JOHNSON. "An improved textile fabric, applicable to the manufacture of varnished cloths, and to other purposes." (A communication.) Dated Jan. 6, 1859.

This fabric presents two different appearances in its face and back: the one surface is composed of a fine warp and weft, and the other of a considerably coarser warp and weft; and the two surfaces are connected together by occasional threads of the finer warp being interwoven with the coarser warp and weft. *Patent abandoned.*

50. J. H. JOHNSON. "Improvements in machinery or apparatus for boring or piercing rocks, applicable also to the dressing or working of stone, and as a power hammer generally." (A communication.) Dated Jan. 6, 1859.

This machine is composed of two principal and distinct parts, the first portion, and the moveable portion. The power consists, 1, of a steam-engine driving a shaft in the ordinary manner; 2, of two parallel beams upon which the moving parts slide, and which are formed with portions of screw threads or racks on their inner faces; 3, of a square sectioned second motion driving shaft for transmitting all the requisite movements. The details are voluminous. *Patent completed.*

51. W. SPENCER. "Improvements in the mode of taking photographic pictures on wood." (A communication.) Dated Jan. 7, 1859.

This consists in the application of the albumen so as to form an insoluble base within the pores of the wood, and the taking of the photographic pictures on wood, the pores of which have been filled with gelatinous matter, and subsequently removing the gelatine from the block without injury to the picture, by the application of a warm solvent. *Patent completed.*

52. I. and A. HOLDEN. "Improvements in means or apparatus employed in preparing and combing wool and other fibres." Dated Jan. 7, 1859.

This comprises various improvements in preparing wool and other fibres, and relates more especially to that method of combing where the fibre is passed through two sets of gill combs. *Patent completed.*

53. E. HEYWOOD. "Improvements in weaving." Dated Jan. 7, 1859.

This consists in the production of double fabrics united in the weaving at parts, and enclosing between them thread or yarn as stuffing, such fabric being adapted for various purposes. *Patent completed.*

54. J. J. FLORENCE. "Improvements in reels or spooling-wheels." Dated Jan. 7, 1859.

This invention is not described apart from the drawings. *Patent completed.*

55. G. K. GEBELIN. "Regulating gas-burners, which he calls the 'Universal Gas Burner Regulator.'" Dated Jan. 7, 1859.

The difference between the ordinary gas regulators with valves and this consists in that the inventor interposes between the valve and the burner an inner perforated chamber, the whole of which will not pass more gas under low pressure than is necessary for the consumption of the various kinds of burners. *Patent completed.*

56. A. BARCLAY. "Improvements in electric and magnetic telegraphs." Dated Jan. 7, 1859.

This invention relates to some extent to two inventions of improvements in electric magnetic telegraph wires or conductors, also improvements in obtaining and distributing or applying electricity and magnetism and in obtaining motive power therefrom, for which the present inventor obtained provisional protection, and it consists of certain arrangements whereby electric and magnetic telegraphs may be rendered of superior efficiency in working. *Patent abandoned.*

57. J. PATERSON. "An improvement in bands and belts for the waist." Dated Jan. 7, 1859.

This consists in rendering leather belts and bands of the waist elastic by introducing one or more pieces of elastic web under one or more covering pieces of leather, and connecting the elastic web to the ends of the leather forming the belt. *Patent abandoned.*

58. H. REYNOLDS. "Improvements in refining and decolorizing saccharine substances." Dated Jan. 7, 1859.

For bleaching and decolorizing saccharine substances the inventor uses stannate of alumina, the stannate and meta stannate of lime, as well as the free meta stannate, and stannic acids, and several other chemical compounds of tin. *Patent abandoned.*

59. W. E. NEWTON. "Improvements in machinery for winding, twisting, and doubling fibrous materials." (A communication.) Dated Jan. 7, 1859.

This invention cannot be described without reference to the drawings. *Patent completed.*

60. H. HARDEN. "Improvements in fire-bars for steam-boiler and other furnaces." Dated Jan. 8, 1859.

This consists in forming and arranging fire or grate bars so that the space between them for the admission of air will pass in a zig-zag line, thus breaking up the grate surface into a series of short parallelograms, and each of which is nearly surrounded by an air space, so that there are no considerable lengths that are unbroken by air spaces as in ordinary bars. *Patent completed.*

61. C. F. VASSEROT. "An improved chain and bucket pump." (A communication.) Dated Jan. 8, 1859.

This invention consists of an iron endless chain armed of long links having double articulation. Each point is rivetted by means of a steel bolt. Each link passes through the centre of a bucket to which it is fixed, the capacity of the buckets being in propor-

tion to the power to be employed for working the apparatus. *Patent abandoned.*

62. D. FRIEDLAUDER. "An improved smoking-pipe." Dated Jan. 8, 1859.

This consists in connecting the bowl of the pipe with its stem or tube, by inserting each into the sides of an india-rubber ball. *Patent abandoned.*

63. T. B. HUBBELL. "An improved trap for rabbits, rats, mice, and other like animals and vermin." (A communication.) Dated Jan. 8, 1859.

This trap is composed of a ring or frame, having connected with it a barb or spear, or barbs or spears attached to a cross piece, and acted upon by a spiral or other spring, so that when the trap is set the barbs or spears fly across the same, and penetrate and hold the animal. The trap is set by a jointed rod or lever which keeps it set while the parts of the rod or lever are kept in a line, but lets it off under the action of the spring as soon as the parts are put out of line by the animal touching one of them. *Patent abandoned.*

64. F. VERSMANN and A. OPPENHEIM. "Improvements in the treatment of various substances by which to render the same uninflamable." Dated January 8, 1859.

This relates to the adaptation of salt of tin, antimony, and zinc, excepting the chloride of zinc, to the articles to be rendered uninflamable. *Patent abandoned.*

65. A. W. WILLIAMSON. "Improvements in condensers for steam-engines and other purposes." Dated Jan. 8, 1859.

These improved condensers consist of a metal case to which a number of tubes are connected at one end. These tubes are closed at their other ends, and contain each of them a smaller tube passing from the closed end of the exterior tubes to a smaller case contained within the case before mentioned. *Patent abandoned.*

66. W. DELANY. "Improvements in submarine boats or vessels, and in apparatus used for working under water." (A communication.) Dated Jan. 8, 1859.

Here a vessel is constructed of an egg-shaped form in transverse section, and running off to a point at both ends, and fitted with one or more keels to keep the vessel steady in the water. The sinking and floating of the vessel are affected by means of tanks for the reception of air or water. The vessel is fitted with a screw propeller for shifting her position. In conjunction with this vessel a diving armour is employed so that a diver may leave the vessel to do whatever may be required. *Patent abandoned.*

67. W. CLARK. "Improvements in purifying natural phosphates of lime." (A communication.) Dated Jan. 8, 1859.

This invention consists of various processes for the purification of natural phosphates of lime to render them more soluble and easier of transportation, which processes are severally applicable according to the variable composition of the phosphates of lime. *Patent abandoned.*

68. R. CONBOLD. "Improvements in instruments for writing and marking, and for the preparation of certain substances for conversion into instruments for writing and marking, and for the application to useful purposes of certain products arising from preparation aforesaid." Dated Jan. 8, 1859.

In order to render reed or cane, or other similar stalks, suitable for conversion into an instrument for writing, the inventor divests the same, or strips thereof, by means of a sharp gaugo-like instrument, of all, or of a sufficient portion, of the internal soft, cellular, spongy material, to render such reed or strips, or portions of reed or cane, when made into pens, either by means of a penknife or other suitable instrument, capable of performing clear and fine writing equal in every respect to the writing produced by the quill and metal pens of commerce. *Patent completed.*

69. J. T. FORSTER. "Improvements in bed births applicable for bunks, hammocks, cots, and other fixed and moveable sleeping places." Dated Jan. 8, 1859.

These improvements in bed births consist in the application of canvas or sacking bottoms, which the inventor nails or otherwise fixes at each end, or at the sides, to form or pieces of wood or other material, shaped and of an extent suitable to keep the canvas distended and in the form required. When used for bed places or bunks on board ship he lashes or otherwise fixes them up at each end to stanchions or other fixtures by which they are stretched. *Patent completed.*

70. W. E. NEWTON. "Improvements in steam-engines and steam generators." (A communication.) Dated Jan. 8, 1859.

This comprises various improvements in marine and stationary engines, and also in boilers by which greater power is obtained from the elastic force of the steam than in engines of the ordinary construction,

and economy of fuel is effected. The details are voluminous. *Patent completed.*

71. W. A. LYTTEL. "Taking the place of springs in many, if not all, of the combinations into which they enter, and also for equilibrating a varying force or weight." Dated Jan. 8, 1859.

This invention is not described apart from the drawings. *Patent abandoned.*

72. R. D. CLEGG. "Improvements in signalling apparatus." Dated Jan. 10, 1859.

This invention is not described apart from the drawings. *Patent completed.*

73. L. A. NORMANDY, jun. "Improvements in the process of distilling and clarifying resinous substances." (A communication.) Dated Jan. 10, 1859.

This comprises, 1, an agitator which being placed in the still, prevents the burning of the substance, and by rakes continually stirring up the bottom, the incrustation of the substance is prevented. The agitator at the end of each heating drives away also all foreign bodies. 2. Of a reservoir into which the resin is led as it leaves the still, and by reason of the different specific gravities of the substances the earthy matters are in a short time deposited therein. 3. Of rotary filters provided with fine metallic cloths or wire gauze, by which all the foreign substances held in suspension in the resin are retained. After these operations the products will be found perfectly purified. *Patent abandoned.*

74. T. J. CLAXTON. "Improvements in the manufacture of boots and shoes." (A communication.) Dated Jan. 10, 1859.

This consists in applying to the toes of boots and shoes a guard or cap of metal, gutta-percha, or india-rubber. *Patent completed.*

75. F. LEHR. "Improvements in machinery for manufacturing metallic ribs for umbrellas, parasols, and other articles." Dated Jan. 10, 1859.

This comprises, 1, a reciprocating jaw or pincer, for feeding and drawing the wire. 2. A shear having a compound motion to cut off the wire. 3. Clumps for holding the wire. 4. Mandrils and turning slubs to bend or coil up the wire to form loops or eyes as required. 5. A mandril and turning slub which takes the end of the wire and turns thereon a loop or eye for the joint by which the end of the rib is attached. *Patent completed.*

76. J. S. MARGETSON. "An improved box or case, suitable for hats, collars, and other useful purposes." Dated Jan. 10, 1859.

Here a piece of card board or other suitable material is cut into a strip and bent into a cylindrical form, after which it is placed into a bag or reticule made in a like form, having a bottom inserted. The upper part of this bag projects above the top edge of the card board, &c., and has eyelet holes through which cords are passed. Upon drawing these cords in opposite directions the mouth of the box is closed. *Patent abandoned.*

77. J. WHITE. "Improvements in cleansing or purifying air, and in increasing or reducing the temperature thereof, and in the application of air so treated to sanatory and other uses." Dated Jan. 10, 1859.

Here the air is caused to pass through channels, into which, and in contact with such air, water is caused to flow in jets or streams; or the air is forced into water in suitable vessels. By impregnating the water thus used with suitable purifying agents adapted to absorb or neutralize impurities combined with the air, putrefaction thereof will be effected, whilst by heating or cooling the fluid thus used, the temperature of the air may be increased or reduced to the extent desired. *Patent completed.*

78. T. H. TOMS. "The employment of certain materials for the production of raised ornamental figures or devices upon textile fabrics." Dated Jan. 10, 1859.

This consists in employing braid, manufactured from mohair coiled round a central core or cord in undulating thicknesses, so as to produce the same form and character as the well-known "coronation braid," and admit of being readily sewn in the requisite figure or design to crape, areopane, cloth, silk, &c. *Patent completed.*

79. E. AGNEW. "Increasing the effect of decorative pictures, landscapes, drawings, and prints, through looking glasses." Dated Jan. 11, 1859.

Here the inventor engraves the outline of a painting, &c., upon the quicksilver, of looking-glasses, or upon any other substance employed in manufacturing the same. He scratches out the quicksilver and applies upon the cleared part the artistic production. *Patent completed.*

80. C. M. KENOT. "Improvements in purifying and decolorizing paraffine, and rendering the same white, hard and sweet." Dated Jan. 11, 1859

To separate the paraffine from the tar, and thus purify it, the inventor applies sufficient heat to the crude paraffine to melt the paraffine which it contains without melting the tar, and he then subjects the melted material to filtration, when the paraffine will pass through the filter, leaving the tar behind. *Patent completed.*

81. J. BIERE, jun. "A self-acting carriage wheel break." Dated Jan. 11, 1859.

This consists in giving to the fore carriage, by slots or otherwise, a longitudinal motion as well as the present rotary one. *Patent completed.*

82. B. ROBBINS. "Improvements in the machinery for working pumps." Dated Jan. 11, 1859.

To apply this invention to (say) a pair of pumps, above the pumps mounted upon suitable framing is a horizontal beam or cross-head, which works on a transverse axle in the centre of its length, and to the ends of which the pump rods are jointed. Formed on, or rigidly attached to, the under side of the balance beam is a toothed segment, which gears into a second toothed segment formed on the head of a pendulous lever, which has its fulcrum below and in a vertical line with the axes of the horizontal beam or cross-head. A vibratory motion in the direction of the length of the balance beam is communicated to the pendulous beam by a transverse horizontal cranked shaft, the crank of which is coupled to its lower limb, or the crank pin may work within a vertical slot formed in the lower portion of the lever. Rotary motion is given to the crank shaft by a spur wheel staked thereon gearing into a toothed wheel on the driving shaft, which is parallel to the crank shaft, and is provided with a fly wheel and so forth. The power is applied thereto by crank handle or other mechanism. *Patent completed.*

83. W. TILLIE. "An improvement in the manufacture of shirts and shirt fronts." Dated Jan. 11, 1859.

This consists in a method of arranging the plaits of the fronts of shirts, so that a less quantity of material is used than in those made in the ordinary way. *Patent completed.*

84. D. E. HUGHES. An improved mode of insulating electrical conducting wires. Dated Jan. 11, 1859.

The principal object here, is to maintain the insulation of submarine telegraph wires after the gutta-percha, &c., has become impaired. One mode by which the inventor attains the desired end, is to insert in the gutta-percha tube that encloses the conducting wires a semi-fluid or soft non-conducting material, which, when the gutta-percha coating is pierced or cut, will ooze out and fill up the fissure. *Patent completed.*

85. B. J. RUBENSTEIN. "Improvements in dentistry." Dated Jan. 11, 1859.

This consists in the application of gold plates, as base pieces beneath artificial gums of hippopotamus tusk (or the tusk of the sea horse,) or ivory. The inventor employs tortoiseshell in certain cases as a substitute for metal plates of various kinds and shapes used in connection with artificial teeth. *Patent abandoned.*

86. R. and W. HAWTHORN. "Improvements in apparatus for promoting combustion, and preventing smoke in coal-burning locomotives, and other steam-boiler furnaces." Dated January 11, 1859.

According to this invention, it is proposed to employ a number of inclined deflecting plates fitted to the doors or other parts of the fire-box or furnace. Deflecting pieces may be interposed between the plates for deflecting the air right and left over the surface of the fuel. It is also proposed to use an arrangement of steam jets to be introduced into the fire-box or furnace through the back part, and on each side of the fire-doors to a little above the surface of the fire. *Patent completed.*

87. C. W. SIEMENS. "Improvements in supports for electric telegraph line wires, and in tools or apparatus to be used in the construction of such supports, part of which improvements are applicable to the joining of pipes and other articles." Dated January 11, 1859.

This invention comprises a variety of details which are described in the specification at too great length to be reproduced here. *Patent completed.*

88. S. VERSMANS and A. OPPENHEIM. "Improvements in rendering fabrics and substances non-inflammable." Dated January 11, 1859.

This consists in rendering fabrics, and other matters of an inflammable nature, non inflammable, by the application thereto of sulphate of ammonia. *Patent completed.*

89. N. P. BURGH. "Improvements in steam-engines." Dated January 11, 1859.

This consists in substituting for the ordinary trunk and piston arrangements a piston having an opening

in the centre for a trunk or tube of a parallelogram or other convenient form to pass through, or slide upon. *Patent completed.*

90. P. BOUCHÉ. "Improvements in the used means for mechanically raising up the gowns of ladies and young ladies." Dated January 12, 1859.

Here a girdle or waist band, made of some strong fabric, is worn under the gown, but independent thereof, being kept round the body of the wearer by hook and eye, or similar attachment, and it has suspended from it two cords or strings, so that both ends of each cord or string hang down. At about equal distances apart on the inside of the skirt four tapes are attached in an upward direction, each of which has formed in it three or four eyet holes, through which are passed the ends of the cord hanging down from the girdle, and having attached to it at bottom one or more wooden or other balls of sufficient weight for keeping the cords distended. The cords may also pass over little wheels or pulleys fitted in a steel or whalebone band attached to the end of the girdle. *Patent abandoned.*

91. W. and W. T. G. BRAY. "Improvements in locomotive and traction engines." Dated January 12, 1859.

This invention is not described apart from the drawings. *Patent completed.*

92. W. OLIVER. "Improvements in boats, and in the mode of propelling them." Dated Jan. 12, 1859.

This consists in employing paddle wheels placed on either side of the boat, and connected through the medium of a crank shaft, to which motion is communicated through the intervention of treadles; the said wheels moving in either direction, and one or both of the same actuated at pleasure by the use of a slide rod motion and disconnecting gear, whilst for the convenience of steering the yoke lines are brought round and secured in the front of the operator, who sits with his face towards the bows. *Patent completed.*

93. J. THOMSON. "Improvements in the manufacture of rings." Dated Jan. 12, 1859.

This relates to the manufacture of what are technically known as "beam rugs," entirely or chiefly from jute or jute-hemp. The essence of the invention is the application and use of jute, or jute-hemp in the portion of the warp which is made to form the pile or shag in the manufacture of beam rugs. *Patent completed.*

94. J. HANDS. "Improvements in preserving or preparing skins intended to be converted into leather, or otherwise manufactured." Dated Jan. 12, 1859.

This consists in a mode of preserving or preparing skins intended to be converted into leather, by subjecting them to the action of gaseous binoxide of nitrogen, nitrous acid gas, and sulphurous acid gas, either separately or combined. *Patent completed.*

95. J. GIBBONS. "Improvements in fixing door and other knobs." Dated Jan. 12, 1859.

Here the outer end of the male screw has a moveable cover applied to it, which is separated from the projection on the fixed rose, and also separate from the female screw in the moveable or covering rose. This cover and the fixed rose are made with notches, slots, recesses, &c., which when they come together and are in use connect the cover with the hollow male screw or other parts of the fixed rose, so that the cover will be prevented turning when the knob is turned, and such connecting of the cover with the fixed rose on the door, may be such that the pull to open the door may be on the fixed rose without acting on the covering rose. *Patent completed.*

96. S. CANNING and H. CLIFFORD. "Improvements in machinery for paying out and for recovering or picking up submarine telegraph ropes, cables, or chains." Dated Jan. 12, 1859.

This consists of one or more grooved pulleys or rollers, each having a jockey pulley or roller with levers working into it. These levers may be either simple or compound, and are raised or lowered by screw or other gear for regulating the speed in paying out or picking up cables, ropes, or chains. On the shaft of each of the grooved pulleys or rollers a break or friction wheel is fixed, fitted with friction straps of wood, leather, &c.; or the patentees fix on each shaft of the grooved pulleys or rollers a friction roller with another intermediate roller running between or on them. This intermediate roller is so arranged that it is capable of being raised or lowered by lever screw or other gear, so as to press down on the other friction rollers, acting both as brake or friction roller, or as the means of connecting together the grooved pulleys or rollers. *Patent abandoned.*

97. T. ELWELL. "Improvements in governors for steam engines and other motive power engines." Dated Jan. 12, 1859.

The patentee claims, 1, the method of constructing governors for steam engines, and other motive power

engines, essentially as described with reference to the drawings. 2. The method of transmitting motion to the expansion slips of steam engines and other motive power engines by means of two pairs of friction surfaces constructed and arranged with other operating parts essentially as described and illustrated in the drawings. *Patent completed.*

98. W. and W. MCNAUGHT. "Improvements in steam engines and in apparatus connected therewith." Dated Jan. 12, 1859.

This invention is not described apart from the drawings. *Patent completed.*

99. S. PHILLIPS. "Improvements in fastenings for securing windows, shutters, and doors, and for other similar uses." Dated Jan. 12, 1859.

This consists in one of its forms of a spring cotter pin made of a length of metal doubled back to form a spring; each end of the metal thus doubled being furnished with half a knob or thumb piece, so that when the spring is compressed the end intended for the hand to act upon has the appearance of being terminated with an ornamental knob or thumb piece. *Patent abandoned.*

100. R. MUSHET. "A new or improved metallic alloy." Dated Jan. 12, 1859.

This consists of an alloy composed of cast iron and metallic tungsten. *Patent completed.*

101. R. MUSHET. "A new improvement or improvements in the manufacture of cast steel." Dated Jan. 12, 1859.

This consists in alloying cast steel with the metallic tungsten, by which the quality of the steel is improved. *Patent completed.*

102. C. N. MAY. "Improvements in sluice valves." Dated Jan. 12, 1859.

This relates to valves having double faces, and which act by pressure approaching either in one direction or the other. Both faces of these valves are brought into contact with the faces of the valve case or passages simultaneously, by reason of their wedge form or inclination to each other, which is also the case with the valve. According to this invention the inventor makes such valves to move on a centre, and disposes them in a semi-circular case, from which they may be removed by a suitable cover. He communicates motion to such valves by a segment of teeth on the periphery and pinion on the handle shaft, or it may be by a tangent screw or other means and whereby to force the valve home or remove it from between the edge faces inclosing or opening such valves. He mounts these valves so as to perform their motion on a centre pin, which the valve embraces sufficiently to form a secure fulcrum, but from which it can be lifted when it is desired to remove the valve from its case for repairs. *Patent abandoned.*

103. C. BRESLAY. "Improvements in coating or covering iron or steel with tin, zinc, or lead, or alloys of shale metals by electrical deposit." Dated Jan. 12, 1859.

The inventor coats iron and steel by the direct deposit thereon (by electrical agency) of the coating metal or alloy which adheres firmly thereto, and no tendency to oxidation is produced, and whereby a firm and durable coating is applied to the iron or steel. For the batteries he employs solutions of caustic soda or potash, instead of acids. *Patent completed.*

104. C. N. MAY. "An improved heat indicator." Dated Jan. 12, 1859.

This consists of an external face or dial upon which are marked figures indicating the degree of heat to which the apparatus is exposed. Internally there is a semi-circular compound lever of brass and steel, one end of which is firmly screwed to the frame or case of the apparatus; the other end, which is free to move, presses upon the short end of a lever, the opposite end of which carries a toothed segment gearing into a pinion on the axis of a pointer which traverses round the dial face. At ordinary temperatures this pointer stands at zero, but the action of heat upon the compound metal bar causes it to expand and press upon the lever, giving motion through the toothed segment and pinion to the pointer, which moves round the dial until it points to a number that indicates the heat of the oven. By this apparatus the heat of an oven may be easily regulated. *Patent completed.*

105. E. A. LIGHTOLLER. "Certain improvements in machinery or apparatus for spinning cotton or other fibrous materials." Dated Jan. 12, 1859.

This consists in the use of a first train of gearing for driving the drawing rollers, and running or drawing out the spindle carriage for the first stretch, when a double-acting coupling is thrown out of gear and into gear with a second or slower motion, so as to turn the drawing rollers and advance the carriage together at a slower speed, during which time the

second stretch is produced, and the drawing rollers can be stopped by a second and independent coupling or catch box, and the carriage still continue its motion outwards until its catch box is thrown out of gear. *Patent completed.*

106. W. BENNETTS. "Improvements in mechanism used for preventing accidents when raising or lowering skips, baskets, or apparatus particularly applicable to mines." Dated Jan. 13, 1859.

Here the skip or basket is so suspended that, immediately a breakage takes place, two projections which move on axes are pressed outwards by springs against the wood framings, and so as to retard and arrest the downward movement. *Patent completed.*

107. W. H. CRISPIN. "Improvements in the construction of ships and other sailing and steam vessels." Dated Jan. 13, 1859.

Here the hull of the ship is constructed of iron, the same being covered internally and externally with wooden planking bolted through the iron and wood, and so arranged as to break joint. The decks may be constructed upon the same principle. *Patent abandoned.*

108. H. CRITCHLEY and S. ELSTON. "Certain improvements in pistons for steam engines, or other purposes." Dated January 13, 1859.

This relates particularly to the arrangement of a series of small cylinders or recesses contained within the interior of the piston; also to the peculiar construction of the several parts connected therewith for the cause of isolating or confining from the action of steam, &c., the means whereby a uniform and continuous pressure is constantly exerted upon interior of cylinder in which such piston works. *Patent completed.*

109. G. SCOPES. "Improvements in apparatus for communicating motion to cots, cradles, and other articles for children's use." Dated January 13, 1859.

This consists in giving motion to cots, &c., by a spring and train of wheels, exactly as the motion is given to the pendulum of a clock. *Patent abandoned.*

110. J. PICKSLRY and R. SIMS. "Improvements in lawn-mowing machines." Dated January 13, 1859.

This consists, 1, in forming the rollers of the full length of the cutters; 2, in disposing the driving wheels so as to work outside the frame, at the same time those wheels are entirely or partially encased so that nothing can come in contact with them; 3, in adapting a carrying or supporting ball or balls in front of the machine as a substitute or substitutes for the wheel or wheels, or rollers of such machines, whereby it is readily and easily suited to operate on large or small lawns, as well as on narrow verges, or borders, or detached spaces; 4, in mounting and fitting the front part of the machine so as to elevate or depress the cutting parts across the whole breadth by means of racks and pinions, screws, or other means for giving simultaneous motion to both sides of the machine. *Patent abandoned.*

111. W. H. MORRISON. "Improvements in wind musical instruments." Dated January 13, 1859.

This applies to those instruments in which the sound is obtained by blowing through a mouth-piece, and consists in adapting to such mouth-piece a flexible and elastic receiver which is to be filled with air by blowing through the opposite end of the instrument, or through an opening otherwise suitably placed. The air thus forced into the receiver will then by the elasticity of such receiver have a tendency to be forced back through the instrument to produce the required sounds; a stop catch, or other regulator may be applied. *Patent abandoned.*

112. D. L. BANKS. "A method of constructing a travelling suspension rail or roadway, applicable among other uses, as a bridge and lifting agent." Dated Jan. 13, 1859.

The inventor describes a method of constructing a travelling suspension rail or roadway which cannot well be explained without reference to drawings. *Patent completed.*

113. J. J. STEVENS. "Improvements in railway signal apparatuses." Dated January 13, 1859.

The patentee claims, 1, the construction of railway signal posts or pillars of wrought or cast-iron; 2, certain means for raising and lowering the lanterns in railway signalling apparatuses; 3, certain means of and apparatus for compensating for the expansion and contraction in the wires, and to work signals at a distance; 4, an arrangement of compensating apparatus to be placed at some point between the ordinary lever and the signal; 5, an arrangement of signalling apparatus to be worked by a passing train, all as described with reference to the drawings. *Patent completed.*

114. F. J. MANCHAUX and E. N. VIBILLARD. "Improvements in breech-loading fire arms and in cartridges." Dated Jan. 13, 1859.

The patentees claim, 1, the use in breech-loading

fire-arms of two plugs, one of which is hollowed out conically, and the other of which is solid, and has a conical exterior entering partly into the hollowed-out portion of the former, the two plugs being connected by a threaded stem and a nut or other equivalent means, so that while the explosive force of the powder is free to drive the inner plug further into the outer plug, and thus close the breech effectually, the inner plug is not at liberty to leave the outer plug when the said force is removed. 2. The use of a projection formed upon the face of the inner plug, in order to provide for the admission of the explosive gases behind the cartridge, whereby the expulsion of the whole of the said cartridge is effected. 3. The construction of cartridges as described with reference to the drawings. *Patent completed.*

115. J. GRIST. "Improvements in machinery for cutting and shaping staves and heads for casks, and for the manufacture of casks." Dated Jan. 13, 1859.

The specification of this invention describes the arrangements of machinery used in detail with the aid of drawings, and is too elaborate to be quoted here at sufficient length for an intelligible abstract. *Patent completed.*

116. W. A. CHADWICK. "A musical instrument chiefly for teaching the intervals of musical scales." Dated Jan. 13, 1859.

This instrument is composed of a hollow box or shell the two sides of which are connected internally by a sound-post; two or more apertures or sound-holes are made in one of the sides, and a base bar is also fixed inside. On the top side of the case the inventor fixes a rail or finger-board with the places at which to stop for notes indicated by pins or studs. A string or wire is attached at one end of the rail and is carried along over the rail and over a bridge near the opposite end thereof, it then passes through a slot in the rail and is attached to a nut, which is adjusted by a thumb screw, so as to regulate the tension of the string. Sound is produced by a bow similar to that of a violin, which will vary according to the part of the string at which it is stopped by the finger. *Patent abandoned.*

117. W. WILSON. "Improvements in machinery for foling bodies of hats and bonnets." (A communication.) Dated Jan. 13, 1859.

This consists chiefly in the use of iron cylinders (lined with lead) supported by an iron frame at each end. Through the length of each cylinder four grooved wooden rollers are placed, so as to cross each other, the ends passing through the iron frame. These cylinders are actuated by suitable mechanism, giving to the grooved rollers the needful oscillating movement, and between these grooved rollers the bodies to be felted are passed. *Patent completed.*

118. T. HERBERT and E. WHITAKER. "Improvements in the manufacture of warp lace." Dated Jan. 13, 1859.

Here three warp threads work with a needle, two of which are called twisting threads and one a pillar thread, and in the working of the machine one of the twisting threads is caused to lap over a needle, and the other twisting thread is caused to traverse under the same, and both threads are caused to rise up and to pass back over the same needle, by which means the first-mentioned twisting thread will be over-lapped from the needle, and the second-mentioned twisting thread will be lapped in the needle, and the two twisting threads will be twisted together. The pillar thread is then caused to lap on the needle, and its lapping is passed under the beard of the needle; but the lapping of the twisting thread is knocked over with the previous loop of the pillar thread. *Patent completed.*

119. O. ROWLAND. "Improvements in laying electric telegraph wires in streets." Dated Jan. 13, 1859.

Here the inventor employs iron troughs furnished with covers so constructed as to form part of the pavement of a street. *Patent abandoned.*

120. J. BARRANS. "Improvements in traction and portable steam engines." Dated January 13, 1859.

This consists chiefly in supporting the boiler and cylinders on a beam or lever; in the application of india-rubber springs to certain parts of the engine and in driving the driving wheels by pinions gearing into cog-wheels fixed to the driving wheels. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated June 29, 1859.

1545. W. and J. WRAY. Certain improvements in reaping machines.

Dated July 13, 1859.

1656. W. A. MUNN. Improvements in reaping machines.

Dated July 20, 1859.

1708. Z. G. A. N. P. ORIOLI. New applications of hypochloride of alumina to bleaching and dyeing, and to the disinfection and preservation of organic matters.

Dated July 21, 1859.

1710. H. B. PRESTON. Improvements in apparatus for superheating steam.

Dated July 28, 1859.

1752. J. ASPINALL. Improvements in evaporating and in apparatus for the same, especially applicable to the evaporation of sugar.

Dated July 29, 1859.

1760. S. WILSON. Certain improvements in the construction of presses for compressing cotton and other articles.

Dated July 30, 1859.

1766. F. HAACK. Improvements in refrigerating apparatus, especially adapted to pumps or other apparatus for the supply of beer and other liquids.

1772. W. JAMIESON. An improved churn. A communication.

Dated Aug. 1, 1859.

1774. W. CAMPBELL and G. WORSTENHOLM. Certain improvements in machinery for the manufacturing of wrought nails, as also in the treatment of the iron from which such or other kinds of nails may be made. A communication.

1776. T. W. G. TREEBY. Improvements in targets.

1780. W. E. NEWTON. An improved mode of and apparatus for making metal cylinders suitable for steam boilers, and other purposes. A communication.

Dated Aug. 2, 1859.

1786. B. DONKIN. Improvements in and in connection with slide and other valves. A communication.

Dated Aug. 3, 1859.

1787. A. PIN. The compounding, preparing, and application of a new sort of paint.

1788. J. HEWETT. Improvements in self-acting water-closets.

1789. W. K. PEACE. An improvement in canisters for hermetically sealing paints and other substances. A communication.

1790. M. MASON. Improvements in machinery for printing, and in apparatus connected therewith.

1791. W. H. TOOTH. Improvements in machinery or apparatus for the manufacture of iron or steel.

1793. J. PETRIE, jun. Improvements in machinery or apparatus for washing wool.

1794. J. H. PHIPSON and W. A. WATSON. A new or improved lubricator for lubricating shafts and other articles requiring lubrication.

1795. W. H. M. BLEWS. A new or improved regulator for gas burners.

1796. E. DOWLING. Improvements in rosettes or ornaments applicable to harness, and for other purposes.

Dated Aug. 4, 1859.

1797. T. LISTER. An improved sanitary water-closet.

1798. J. HORTON. A new or improved water-gauge for steam-boilers.

1799. R. A. BROOMAN. Improvements in mills for grinding coffee, corn, and other substances. A communication.

1801. F. WALTON. Improvements in the manufacture of ornamental fabrics suitable for book binding and other uses, and in machines employed in such manufacture.

Dated Aug. 5, 1859.

1803. E. B. GOWLAND. Improvements in pianofortes.

1804. E. SWAINSON. Certain improvements in looms for weaving.

1805. N. D. MAILLARD. Improvements in compasses for indicating the course and time of ships at sea, without the use of needles or magnets.

1807. N. BERRY. An improvement in the manufacture of knitted fabrics. A communication.

1809. W. E. NEWTON. An improvement in billiard and hagatelle cues. A communication.

1810. F. W. BEAUMONT. A hydraulic apparatus, applicable to transmitting, regulating, and measuring the supply or flow of liquids.

1811. W. THOMPSON. An improved printing telegraph.

Dated Aug. 6, 1859.

1815. A. B. CHILDS and L. D. OWEN. Improvements in machinery for cleaning grain and seeds from snout and other extraneous matter.

1816. A. T. DE LIALE. Improvements in clarifying and decolorizing solutions of sugar and other liquids.

1817. E. A. Suwerkrop. Improvements in reaping and mowing machines. Partly a communication.
 1818. A. F. Delannoy. Improvements in lubricating the axles or journals of wheels, also applicable to lubricating apparatus for the transmission of motion in general.
 1819. J. W. Welch. Improvements in machinery or apparatus for sizing or dressing yarns or threads for weaving.
 1820. E. T. Hughes. Improvements in machinery or apparatus for manufacturing chenille. A communication.

Dated Aug. 8, 1859.

1821. J. Weston. Improvements in breaks for railway carriages, and in the method of applying the same, and in conveying signals from one part to another of the same train, parts of which are applicable to breaks for other purposes.
 1823. H. Liddle. Improvements in machinery or apparatus for polishing yarns or threads.
 1829. J. H. Johnson. Improvements in apparatus for steering ships, applicable also in all cases where a rotatory or partial rotatory motion is required. A communication.

1831. B. S. Cohen. Improvements in ever-pointed pencils.

1833. T. and R. Blinkhorn. An improved composition for removing scale or fur from the interior of boilers, and also for preventing the formation of scale or fur therein.

Dated Aug. 9, 1859.

1835. T. Dunn. Improvement in machinery and apparatus for elevating and regulating the level and flow of liquids, part of which is applicable for propelling vessels.
 1837. P. F. Rolland. A new electric telegraph.
 1839. I. Mitchell and S. Lister. An improvement in apparatus applicable to machinery for spinning fibrous materials.

1841. J. B. Badcock. Improvements in bustles and skirts. A communication.

1843. J. D. Bryant. Improved superphosphate of lime.

1845. B. Browne. Improvements in the manufacture of paints and pigments. A communication.

1847. W. Mac Lellan. Improvements in parts of the permanent way of railways. A communication.

Dated Aug. 10, 1859.

1849. W. Muir. Improvements in machinery for communicating motion to foot lathes and other machines to be worked by treadles.

1851. W. K. Westly. Improved machinery for combing, heckling, and preparing to be spun flax and other fibrous substances.

1853. A. Shaw. Certain modes or methods of preparing sheep or other skins or pelts, or the linings thereof, and for raising nap on the same, and also for preparing the said skins for kid leather, and for enamelling and japanning the same.

1855. J. D. Bryant. Improved superphosphate of lime.

1857. W. Mac Lellan. Improvements in parts of the permanent way of railways. A communication.

1859. J. D. Bryant. Improved superphosphate of lime.

1861. W. K. Westly. Improved machinery for combing, heckling, and preparing to be spun flax and other fibrous substances.

1863. A. Shaw. Certain modes or methods of preparing sheep or other skins or pelts, or the linings thereof, and for raising nap on the same, and also for preparing the said skins for kid leather, and for enamelling and japanning the same.

1865. J. D. Bryant. Improved superphosphate of lime.

1867. W. Mac Lellan. Improvements in parts of the permanent way of railways. A communication.

1869. J. D. Bryant. Improved superphosphate of lime.

1871. W. K. Westly. Improved machinery for combing, heckling, and preparing to be spun flax and other fibrous substances.

1873. A. Shaw. Certain modes or methods of preparing sheep or other skins or pelts, or the linings thereof, and for raising nap on the same, and also for preparing the said skins for kid leather, and for enamelling and japanning the same.

1875. J. D. Bryant. Improved superphosphate of lime.

1877. W. Mac Lellan. Improvements in parts of the permanent way of railways. A communication.

1879. J. D. Bryant. Improved superphosphate of lime.

1881. W. K. Westly. Improved machinery for combing, heckling, and preparing to be spun flax and other fibrous substances.

1883. A. Shaw. Certain modes or methods of preparing sheep or other skins or pelts, or the linings thereof, and for raising nap on the same, and also for preparing the said skins for kid leather, and for enamelling and japanning the same.

1885. J. D. Bryant. Improved superphosphate of lime.

1887. W. Mac Lellan. Improvements in parts of the permanent way of railways. A communication.

1889. J. D. Bryant. Improved superphosphate of lime.

1891. W. K. Westly. Improved machinery for combing, heckling, and preparing to be spun flax and other fibrous substances.

1893. A. Shaw. Certain modes or methods of preparing sheep or other skins or pelts, or the linings thereof, and for raising nap on the same, and also for preparing the said skins for kid leather, and for enamelling and japanning the same.

1895. J. D. Bryant. Improved superphosphate of lime.

1897. W. Mac Lellan. Improvements in parts of the permanent way of railways. A communication.

1899. J. D. Bryant. Improved superphosphate of lime.

1901. W. K. Westly. Improved machinery for combing, heckling, and preparing to be spun flax and other fibrous substances.

1903. A. Shaw. Certain modes or methods of preparing sheep or other skins or pelts, or the linings thereof, and for raising nap on the same, and also for preparing the said skins for kid leather, and for enamelling and japanning the same.

1905. J. D. Bryant. Improved superphosphate of lime.

1907. W. Mac Lellan. Improvements in parts of the permanent way of railways. A communication.

1909. J. D. Bryant. Improved superphosphate of lime.

1911. W. K. Westly. Improved machinery for combing, heckling, and preparing to be spun flax and other fibrous substances.

1913. A. Shaw. Certain modes or methods of preparing sheep or other skins or pelts, or the linings thereof, and for raising nap on the same, and also for preparing the said skins for kid leather, and for enamelling and japanning the same.

1915. J. D. Bryant. Improved superphosphate of lime.

1917. W. Mac Lellan. Improvements in parts of the permanent way of railways. A communication.

1919. J. D. Bryant. Improved superphosphate of lime.

1134. W. E. Newton. Steam gauge. A communication.

1135. W. E. Newton. Fish hooks. A communication.

1296. A. V. Newton. Rivets and bolts. A communication.

1327. E. Breffit. Corks.

1334. J. L. Norton. Fabrics.

1694. A. Phillips. Fabrics.

1738. J. Gillott and J. Morrison. Penholders.

1765. J. Wood. Truss for hernia.

1777. T. G. Messenger. Horticultural buildings.

1803. E. B. Gowland. Pianofortes.

1817. E. A. Suwerkrop. Reaping and mowing. Partly a communication.

- The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

- Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed August 19, 1859.

LIST OF MISCELLANEOUS TENDERS INVITED, AND ENGAGEMENTS OPEN.

The tenders and engagements which appear in this weekly list are not repeated in succeeding numbers.

RAILWAY, *Llynri Valley*.—Divisions of portions of the line. Plans at the Company's Office at Porth Cawl. Tenders to August 31st.

DREFFNER, *Drop Redoubt, Dover*.—Candidates desiring to tender for the above works must signify their intention at the Royal Engineer office, Dover, before September 23, where terms may be known. A meeting of candidates, to elect a surveyor, will be held at the Royal Engineer Office, Dover, at 12 o'clock on Thursday, August 25th.

GUARD HOUSE, *Dover*.—Candidates desiring to tender must signify their intention at the Royal Engineer office, Dover, until August 27th. Bill of quantities, half-a-guinea. Tenders to September 6th.

MATERIALS, *Dover*.—And performance of such bricklayers', masons', paviours', carpenters', slaters', plasterers', plumbers', painters', glaziers', and paper-hangers' work required by the Royal Engineer Department at various stations of the Dover district from September 1859 to March 1860. Only one contractor will be accounted for all the trades at each station, and parties tendering must state according to the printed directions, the rate at which they are willing to perform the work. Printed schedules and all particulars at Royal Engineer office, Hythe, to September 5.

HYDRAULIC MAIN, *Sowerby Bridge*.—36 feet long, and 30 inches diameter, for 20 reorts; also exit, H and Dip pipes, all complete. Plans, Sowerby Bridge Gas Works. Tenders to August 29.

GASHOLDER, *Teignmouth*.—With cast-iron tanks, a vertical condenser, a scribbler, governor, &c. Plans, &c., office of Mr. Wm. Cotton, Surveyor, Teignmouth. Tenders to August 30th.

CHURCH, *Downton, Herefordshire*.—Plans, &c., office of Mr. S. Poutney Smith, Shrewsbury.

CHAPEL, &c., *Edinburgh*.—For the erection of a chapel, school, and schoolmaster's quarters at Piershill barracks, Edinburgh. Tenders to the Director of Contracts, War Department, Pall Mall, London, September 12.

PARSONAGE, *Kirtan Lindsey, Lincolnshire*.—Plans, &c., with Rev. F. Stuart, Kirtan Lindsey. Tenders to September 6th.

SCHOOLS, &c., *Liverpool*.—For the erection of parochial schools and teachers' residences for the parish of West Derby, near Liverpool. Drawings, specifications, &c., Mr. H. P. Horner, architect, 10 Hasnett-street, Liverpool, where tenders. No date supplied.

SCHOOLS, *Brandon, near Durham*.—Plans at the office of Mr. Dobson, architect, Newcastle-upon-Tyne, and at the Rectory, Brancepeth, near Durham. Tenders to Aug. 21.

ASYLUM, *Alterations, Worcester*.—Including reservoir, pump-well, water tower, steam engine, boilers, &c. Plans at office of Mr. E. L. Williams, C.E., Diglis, Worcester. Tenders to September 3rd.

HOUSES, *Spaldington, near Horden*.—Upon the estate of Sir Henry Mervyn Vavasour, Bart., at Spaldington. Plans, &c., Messrs. Stephens and Robinson, architects, 17 Tomet-street, Derby. Tenders to September 7th.

LAUNDRY, *Chichester Barracks*.—Plans, &c., Royal Engineer's Office, Portsmouth. Tenders to September 6th.

CART SHED AND TOOL HOUSE, *Poplar District*.—For the erection and completion of a cart shed and tool house, in the stone yard, St. Leonard's-road, Bromley. Forms of tender, Mr. C. C. Ceely, clerk to the board, East India Dock-road; where tenders September 6.

SEWERAGE, *Crumphall*.—250 yards of Tyson-street. Plans, &c., of Mr. Bell, surveyor, 51 King-street, Manchester. Tenders to the chairman, J. Knott, Esq. (Overseer's office) Crescent-road, Crumphall. Tenders to September 10th.

SEWERS, *Poplar District*.—For laying down sewers in the parish of Bromley. Willis-street and Desert-street. 65 ft. run, 12 in. patent pipe; Tetley, Randall, and Cawder-street, 65 ft. run, 12 in. patent pipe; with the requisite gullies and connections. Tenders, noon, September 6, with Mr. C. Ceely, clerk to the board, East India Dock-road, where forms of tender.

FIRE DRAINAGE, *Trenttham, North Staffordshire*.—For excavating and laying down about 1,600 yards of 18-in. drain pipes. Apply to Mr. Roberts, Trenttham office. No date given.

METAL ROLLER.—One to undertake the management of a mill. Apply to Mr. S. Walker, Rolling, Tube, and Wire Mills, Lower Fazely-street, Birmingham.

MACHINIST.—One accustomed to fine drilling, acquainted with perforating tools, and accustomed to making apparatus for working same. Address by letter, C. B., 250, Daily Post Office, Birmingham.

PROBLES AND UNDERHANDS.—Good characters for steadiness and ability necessary. Apply to Mr. J. Broad, Lower Furness Iron and Steel Works, Ulverston.

LAMP MANAGER.—One who understands the manufacture of lamps and arrangement of stock. Apply to J. Taylor and Sons, Warwick-lane, Newgate-street, London.

GAS CHANDELLER MAKERS.—Several first-rate, and two burnishers. Apply to Benja. Vickers, Atlas Works, Sheffield.

MILLWRIGHT.—To superintend the machinery and make patterns. Apply to E. J. Hunt, Prince of Wales Ironworks, Millwall, Poplar, London, E.

HEAD FOREMAN.—Thoroughly acquainted with smith's work, and the fitting necessary for iron bridges, iron roofs, tanks, &c. J. H. Porter, Ironworks, Gas-street, Birmingham.

ENGINEER'S DRAUGHTSMAN.—A draughtsman of superior ability and great experience in marine engine work. Applications, with every particular, E. D., care of Messrs. Hammond and Nephew, 27 Lombard-street, London, E.C.

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, SEPTEMBER 2, 1859.

THE NATIONAL DEFENCE
COMMISSION.

HER gracious Majesty, having thought it expedient, for divers good causes and considerations, that a Commission should forthwith issue, and that inquiries may be made by her Commissioners into "the present state, condition, and sufficiency of the fortifications existing for the defence of her United Kingdom, and of [sic] examining into all works at present in progress for the improvement thereof, and for [sic] considering the most effectual means of rendering the same complete, especially all such works of defence as are intended for the protection of our Royal arsenals and dockyards in case of any hostile attack being made by foreign enemies both by sea and land," has appointed Major-General Sir Harry D. Jones, K.C.B., Major-General Duncan A. Cameron, C.B., Rear-Admiral Elliot, Major-General Sir Frederick Abbott, K.C.B., Captain Astley Cooper Key, R.N., C.B., Colonel J. H. Lefroy, and James Fergusson, Esq., to be her Commissioners for the purpose of such inquiries as aforesaid; and for their assistance in the due execution of these duties has made choice of Major William Francis Drummond Jervois, to be Secretary to this Commission, and to attend them and aid them with his services and assistance.

According to our great national defence authority—the *Times*—"the constitution of this Commission provides a very fair representation of all branches of the two services; nor will it escape notice that Mr. James Fergusson participates in the honour of the appointment, so that the 'Perils of Portsmouth,' if they really exist, can now be taken into effectual consideration." Now, against Mr. Fergusson's appointment we have not a syllable to say, for there is probably not a civilian in England who has studied the subject of national defences more closely or more intelligently than he; and we happen to know that he has very recently gone minutely into the question in an article which has excited a good deal of attention—in our own columns and elsewhere. But we certainly must say that by placing a single civilian only upon the Commission, and by making "fortifications" the only subject of its inquiry, the Government have gone a very short way towards satisfying our desires in this matter. Without asking whether in Sir Harry Jones, General Cameron, Sir Frederick Abbott, and Colonel Lefroy, we have four of the foremost military men of the age, or whether Admiral Elliot and Captain Key are to be ranked among our greatest naval authorities, we are entitled to say that four military and two naval officers, with a single civilian thrown in, cannot possibly arrive at a satisfactory solution of the vast question of our defence.

We are prepared, in fact, to assert that by the appointment of the Commission now before us, the attention of which is to be confined to land defences, the greatest causes of our recent fear and dread are ignored. Were the times not exceptional—did we apprehend nothing more now than our fathers of a century since had to look for—a mere military and naval Commission might answer our purpose. But the only men in whom we can now confide are men fit to grapple with the altered condition of things that characterizes this strange age. The very first thing we want decided is, how we shall meet

the new forms of danger to which the creation of steam fleets has exposed us. Will this Commission settle that question for us? Then, again, we want to know what is to be done in regard to iron-plated vessels—whether we are really to begin building them, or stick to our wooden walls. Will this Commission resolve us this doubt? Then, again, we wish to be informed how many millions we are to spend on our new rage for line-of-battle ships, and whether gunboats are really to be held in esteem or not. Will this Commission say yea or nay to these things? And so we might go on naming subject after subject in reference to which all the intelligent people in the country stand dumbly doubting and waiting, but upon which this Commission cannot possibly yield us any kind of reliable conclusions. In short, in an age when the progress of science is changing all things, Her Majesty's Ministers have appointed a Commission which, it may with certainty be predicted, will end by prescribing change in nothing. When a strong apprehension of danger can prompt us to no better action than this, we may well pray that evil may be kept far from us. If we have nothing more in the shape of genius to oppose to Louis Napoleon than this Commission presents, we have indeed cause to hope that the powers of the two nations may not be measured against each other in our time.

RIFLED ORDNANCE.

MR. SIDNEY HERBERT, our War Minister, and his colleague, Lord Ripon, have made a ready and graceful concession to the demands of the press, and are taking steps to ascertain the best means of rifling our present cast-iron ordnance without delay. This they have set about in a very novel manner; and, as a temporary expedient, designed to answer a temporary purpose, the plan they have adopted is certainly not a bad one. Knowing but little practically upon the subject themselves, they have turned sharp round upon the gentlemen who profess to understand it, and asked them to show how it is to be done, giving each of them an ordinary 32-pounder to do the best they can with. "Here 'Sir William'—says my Lord Ripon to our new Newcastle Knight—"take you this gun, and rifle it with your cunningest skill, giving it four grooves or forty as may please you; and here, Mr. Lancaster, is yours, to receive whatever overruling you may think fitting; and here yours, Mr. Whitworth, to be bored as many-sided as you may desire; and here yours, Mr. Nasmyth, and yours, Mr. Thomas, and yours, Mr. Haddan, and yours, Mr. Britten, and yours, and yours, and yours." We do hear that no less than fourteen gentlemen, all of whom have professed themselves very clever at this sort of thing, are now boring, and planing, and firing away, with the view of producing the best attainable result with their guns by an appointed day. Then they will meet at Shoeburyness, each with his own gun, and his own special projectile, to make the best practice possible, each in presence of all the others.

Already we have heard (in the *Times* Naval and military intelligence) of mysterious results attained by Sir William Armstrong, who is said to have fired over 3,400 yards with an ordinary 32-pounder, rifled by himself, hitting a target six feet square at every shot with what the writer calls a "terrific aim" (by which he means, we presume, an "aim with a vengeance.") This is much too good to be true, we fear, for, if true, it would go a long way towards eclipsing the wonderful breech-loading gun itself, and thus saving us all the expense of manufacturing that very costly article.

What the result of this great and singular

experiment will be when all the rifled 32's are brought together, it is impossible to predict. That it will be possible to rifle the present cast-iron guns with great advantage we do not for a moment doubt, inasmuch as great results have already been attained by some experimenters. But it appears certain to us that if the guns are to stand, and be reliable after they are rifled, then the rifle grooves must neither be deeply impressed nor have a great turn; otherwise the guns will infallibly burst with elongated projectiles and ordinary charges of powder.

Our opinions of the various systems of Sir W. Armstrong, Mr. Lancaster, and Mr. Whitworth are pretty well known; but of Mr. Haddan's plan, which seems to us not ill-adapted to the present case, we may here say a few words with advantage. Mr. Haddan forms in the gun three shallow "curves," sinking only to about 5-16ths of an inch beyond the circular bore, and wearing off until they lose themselves in the circle of the bore. To these curves he gives a very slight twist—only about one turn in sixty feet, we believe, which is less than that given by any other of the competing gentlemen. His projectile has three swells or projections upon it to take into the grooves, and is formed with a conoidal head and a taper towards the rear end, on which end is placed a simple ring-formed wad. The projectile goes freely into the bore, and when the charge is exploded the centre line of the projectile is compelled by the conditions of the case to occupy the centre line of the gun, and pass out in that position. The projectile can be made as cheaply as any ordinary round shot or shell, being simply of cast-iron; and no great nicety is necessary in adjusting the size of the projectile to that of the gun. The wad is caused to clean out and lubricate the gun at each discharge, and both the gun and the projectiles may be used as roughly as ordinary guns, shot, and shell. Six months since an ordinary 68-pounder gun rifled on Mr. Haddan's plan projected a 90 lb. elongated shell with considerable truth of aim over an average distance of nearly 3,000 yards, with an elevation of ten degrees and a charge of powder of ten pounds, being, as will be seen, only 1-9th the weight of the shell. This was very good practice, and we shall not be surprised to learn that the same system comes out well from the coming test. At any rate, the method of rifling appears to us to be second to none, except perhaps the Lancaster system, for the present exceptional purpose of converting our old smooth bores into rifles, as it will in all probability weaken and distress the gun but slightly.

But however imperative and urgent the task of rifling our old guns may be, it must not be forgotten that when this is done we, as a scientific and enterprising people, and as rivals, in a certain sense, of a scientific and enterprising empire, shall still have much to do. The whole subject of rifled cannon is at present in a most unsatisfactory condition. We have not even so much as brought together anything like an authoritative collection of the principles involved, or which ought to be embodied, in such ordnance. So that even when, by independent invention, a new gun is brought to our notice, we know not what tests to apply to it. Our proceedings with the Armstrong gun illustrate this in a remarkable manner. Here we have not only adopted a gun which soldiers and sailors smile at, as a weapon entirely unsuited to the exigencies of actual warfare, but have put the inventor of it into supreme authority over the whole of the rifled ordnance department; so that nothing is left to us but to put as good a face upon matters as we can, and humbly read in the newspapers that "in

"Woolwich Arsenal the most implicit confidence is placed in the judgment of Sir William Armstrong"—while we know that nearly every military man in the establishment is moodily submitting to what is just now inevitable, but is at the same time eagerly waiting to hear that Sir William's splendid and delicate machine is to be superseded by what they would call a gun. We say not that Sir William is wrong and the military men are right. We should be grieved indeed to see a too hasty stop put to the proceedings of our new and unquestionably able rifled-ordnance engineer; but what we do wish to see is a speedy attempt to bring the whole subject better under the control of our knowledge and experience. With the view of furthering this object we will next week quote a chapter on the subject from Mr. Lynall Thomas's new work on rifled ordnance. It contains considerations which deserve the best attention of our war authorities.

THE NEW WORKS DEPARTMENT OF THE ADMIRALTY.

THE damaging letters which Mr. Murray and his colleague Mr. Bowman have published in our columns have brought such a weight of discredit upon the writers that other official gentlemen do not like trying their hands on similar productions. Consequently, although strong objections to our recent article on the New Works Department of the Admiralty have been expressed, no written protest has been received by us from any person entitled to speak upon the subject. But although we have had no silly letter sent to us in this case, a wise and temperate remonstrance has been made, and we feel fairly called upon to deal with the explanations that have been offered. And let it be understood that we have received "explanations" only—not contradictions. Indeed, we were not open to mere contradiction; inasmuch as, while our general charges were based upon "complaints" which had been made to us by others, the particular circumstances to which we referred were witnessed with our own eyes. Passing by, for the moment, our general reflections upon the department, let us now glance at the several objects respecting which we made complaint.

In the first place, with regard to the covering in of the space between the storehouse and the forge at Sheerness Yard, a very weighty allegation is made, viz., that this objectionable proceeding was resorted to under the pressure of anticipated necessities during the Russian war. It is not denied that in an architectural sense the proceeding was a most objectionable and offensive one; but it is said, that when the Russian war broke out, and our fleets were sent into the Baltic, the want of means for repairing our steam-ships at Sheerness was so strongly felt, and the yard offered so little ground to work upon, that the conversion of the space in question into a boiler shop could scarcely be avoided, and Sir James Graham and his colleagues therefore unhesitatingly authorised it. There is unquestionably much force in this statement; and although we still fear the step was taken with less regard than might have been shown to æsthetic principles, we very cheerfully publish the explanation. As to the jetty which now stands out black in front of the dockyard, and which was the second thing mentioned by us with disapprobation, we are assured that the existence of some structure of the kind was an absolute necessity. The last thing to be noticed is the tramway laid down for the boiler carriages to run upon. The bad state of portions of this road is fully admitted—so fully that the executive officers at Sheerness have been blamed for it by their

superiors. It is represented, however, that the method of constructing tramroads of wood blocks in the manner explained in our former article has been resorted to because of the rapidity with which granite roads wear and break up near the joints, and also because in the construction of the wooden roads much timber which would otherwise be sold as waste can be turned to account. It is further said that a road formed of wooden blocks placed on end in iron frames, and bedded on a basement of concrete, has answered the purpose very well in places where sufficient time has been allowed for the proper consolidation of the concrete. We must also remark that the plan of transporting and storing boilers which we attributed to the chief engineer of Sheerness dockyard is claimed by the Department of Works at Somerset House, although the Directors of that department bear the highest testimony to the zeal and ability with which this and many other plans for saving time, labour, and expense have been carried out at Sheerness dockyard by Mr. Blaxland. So well, indeed, have the factory operations been conducted at that yard, that the establishment has been brought into a very high state of efficiency.

It will be observed, from what we have hitherto said, that, having no interests but those of truth and fairness to serve, we are not in the slightest degree disposed to do injustice to the Directors of the Admiralty New Works. Complaints from many quarters reached us, and we willingly gave voice to them; statements opposed to those complaints are now made to us, and we as willingly give them publicity. In consequence of what we have recently learnt we are in a position to say further that Colonel Greene, the Director of Works, and Mr. Scamp, the Deputy Director, have been neither dilatory nor supine in the performance of their arduous and responsible duties. It must not be forgotten that, although they are the heads of a Department, they have to perform their duties under the sanction of the Board of Admiralty, and have to submit to all the delays and obstructions which invariably occur under such circumstances. This fact goes a long way in explanation of the "complaints" which reached us, and which we thought it well to express. We now have, indeed, reason to believe that the Department has been actively conducted—that an enlightened regard to the altered circumstances of our dockyard establishments has been paid by Colonel Greene and Mr. Scamp—that the introduction of many great and real improvements have originated with them—and that numerous causes of complaint against them disappear when circumstances over which they had no control are properly understood.

There is one other point, upon which, as it had very much to do with the *tenor* of our former article, we cannot with justice be silent. It is, the alleged independence with which the Directors of Works are said to conduct their business. We have not a syllable to retract from that severe introductory paragraph with which we commenced our former article. It is a shameful thing for men to manage the affairs of the nation with an utter disregard of the nation's welfare. In heaven's name let us not fail to exclaim against that sleek and sleeping officialism which is so full of peril to us as a people. It must be fought against, wherever found, by every one of us who can manage to keep a little patriotism alive in him. But, as the thing itself is so base and ruinous, it must not be lightly imputed; and for this reason we accept the protest made against the passage which we quoted from the Report of the Committee on Dockyard Economy and Efficiency in our former article. We are asked to believe

that Mr. Murray and his friends were as far from the truth on that point as they were on nearly every other. Why, it is inquired, should we—who have so strenuously protested against the constitution of that Committee, and shown its unfitness to deal with our great naval establishments—why should we esteem it competent to sit in judgment upon the New Works Department of the Admiralty? Is Admiral Smart, or Mr. Laws, or Mr. Murray, the man to pronounce opinions upon roads and buildings; or is that versatile genius whom Mr. Lindsay dug up somewhere equal to this as well as to so many other imposing tasks? Our reply is, the Committee was as little fit for this business as for any other; but that is no reason why they might not have gone right *by chance*; and we certainly never implied that they went right otherwise. The truth is, this question—whether Colonel Greene and Mr. Scamp have sufficiently consulted with the officers of the dockyards—is one which must at present remain open. They strongly assert that they have; others think they have not; who shall decide? All we can say is, we most sincerely trust that whether they have or have not in the past, they will leave no room for doubt upon the subject in the future.

THE NEW BRONZE COINAGE.

WITH regard to the expected issue of bronze coins from the Mint, we believe it may be taken for granted that some little delay will arise. In the first place the design has to be determined on—whether a public competition of engravers be invited or not; and in the next a considerable time must be allowed for the "getting up" of a sufficient number of dies to enable the work of coinage to go on on a large scale without chance of interruption. It is not too much to ask of the public that time be given for the maturing of the plans of those officials and others in whose charge the working out of the Government resolve with respect to the new coinage will be placed. The public will grant reasonable indulgence no doubt, but they will not like to have valuable time wasted; and whilst promising the Treasury and the Mint that it will not be expected of them to produce bricks without straw, it must be understood that they certainly will call down upon themselves popular opprobrium if, having money, material, and appliances, they do not use diligence in turning them to proper account. If the new coins make their appearance with the new year there may not be great reason for fault finding; but beyond that time there can, we think, be no rational excuse for delaying their publication.

It is whispered that the device for the reverse of the three denominations of coins is to be that of Britannia, scantily clad, seated uncomfortably on a ledge of rock, with shield and trident, as now seen on the effete copper tokens. If there be truth in this whispering we can only say that we are very sorry for it. Why not have something new? Is there such poverty of inventive skill among engravers and others that there is danger of getting something worse? Has no one in the kingdom talent enough to sketch out a design which should be at once symbolical of the ocean sovereignty of Great Britain and a fit impression for a coin? Alas for us if it be so! But it can scarcely be credited that a gentleman of so much taste as the present Chancellor of the Exchequer will quietly assume so discreditable a state of things, and thus allow King Charles II. to be the author, or at least the patron, of a design for the new coinage of Victoria! We put it to the right hon. gentleman to interpose the weight of his judgment and authority, and to prevent a

national disgrace. The opportunity is a great one, and it ought not to be lightly treated. Probably, when the next new coinage—be it decimal or otherwise—issues from the Mint, we of this generation shall have passed away, and it behoves us to leave behind us proofs that we were not deficient of taste, skill, or public spirit.

It would not be amiss if—since the new pieces of mixed metal are to be much smaller than the old pieces of copper—their value were to be imprinted upon them; and this might be done *à la* shilling and sixpence, if no better design is to be employed. The simple wreath of oak and laurel surmounted by the crown, and enclosing respectively the words, "One Penny," "One Halfpenny," and "One Farthing," with the date 1860 below, would be a decided improvement upon the almost nude allegorical Britannia, than which, in short, nothing can be worse. We are urgent upon this matter, because in our columns a reformed coinage was originally advocated, and to some extent our credit is involved in its satisfactory consummation. Parliament is not sitting, unfortunately, or some member numismatically learned might ask the question—"What impressions are to be given to the new bronze coins?" The public would like to have it answered, and so should we.

THE WESTMINSTER CLOCK.

MR. LOSEBY's able letter, which first appeared in this Magazine on August the 12th, has been made the occasion of a very instructive quarrel. On the appearance of Mr. Loseby's letter, Sir Charles Barry explained (in a letter published in our last number) that the heavy clock hands which Mr. Denison now condemns were made with his (Mr. D's) approbation, and that he alone is therefore responsible for them.

Those of us who knew Mr. Denison of old, and to whom his blatant style is painfully familiar, anticipated the sort of thing that would follow. On the 25th forth it came (in the *Times*), coarse and copious as ever:—"Our great architect's head has evidently been turned by his 'unusual run of luck. Hitherto he has been 'getting that pleasant little *solatium* which 'architects do, on all his extravagances and 'miscarriages at Westminster, while other people have got the blame. Architecture, ventilation, clock-making, dial-making, bell-hanging, it is all the same." Then off he goes with paragraph after paragraph, to show that Sir Charles Barry is a nepotist—an imposter—a liar—and a scheming scoundrel generally. Having settled these little points with vehemence, he goes more quietly to work, and tells us leisurely that from the time when he was first asked to take this business in hand until now, there has not been a single stage in it in which he has not been put to needless trouble, and the nation to needless expense, by Sir Charles Barry's carelessness and blundering. The design of the clock had to be altered to suit his walls; the clock-shaft was too wide one way and too narrow the other; the great bell could never have been got up at all if it had been made of the usual shape, though he himself fixed the weight, and therefore the size of it, in 1846; the clock was kept back for years because it has to stand over the only place where the bell could be got up by any contrivance; the clock-room was too dark to work in; the staircase is now in the only dark corner of the tower, and has to be kept lighted with gas, and has windows opening into the ventilating chimney, where charcoal is burnt while Parliament is sitting; "and so," says this careful gentleman, "I might go on with a number more of obstructions, moral and physical, which I

"have had the trouble of encountering and the 'satisfaction of defeating." About a twentieth part of his epistle is occupied with his reply to Sir Charles Barry's letter, which reply is in the following words:—"To his statements that I 'approved those hands as ultimately made by 'him, and that I fixed them, or saw them before they were fixed, or had anything whatever to do with the fixing, I give the flattest 'contradiction within the compass of the English 'language."

The next day, Sir Charles Barry—passing by the rude abuse of his antagonist—comes forward with a quiet but crushing rejoinder in the shape of the following "declarations":—

"We, the undersigned, who have been employed in executing the work of the hands of the great clock of the New Palace at Westminster, do hereby declare that we have acted throughout under the directions of Mr. Denison in that work, and that after having submitted to that gentleman two pattern minute hands, exhibiting various modifications for lightening the weight, we succeeded in producing a hand which he said entirely met his wishes. He also said that he did not imagine that they could have been made so light in weight, and desired that the remaining three hands might be proceeded with, in accordance with it in all respects."

"THOMAS QUARM, Clerk of Works.

"JAMES JAMES, Engineer and Contractor for the Hands, Broadwall.

"HENRY HART, Foreman to Mr. James."

"We, the undersigned, having this day witnessed the weighing of one of the minute hands of the great clock of the New Palace at Westminster, do hereby declare the weight of that hand, and its external apertures, the counterpoise, to be as follows:—

	Cwt.	qrs.	lbs.
Entire weight of hand and counterpoise	2	1	22
Weight of counterpoise beyond the axis of the arbor or spindle (deducted)	1	0	25
Net weight of the hand	1	0	25

"CHARLES BARRY.

"THOMAS QUARM, Clerk of Works.

"J. JAMES, Engineer and Contractor, Broadwall.

"HENRY HART, Foreman to Mr. James."

These, of course, bring out Mr. Denison again; but this time he certainly is not happy in his own defence. He begins by saying he has "a short but tolerably decisive answer to "give to Sir C. Barry and all his certificates "from the people who did the hand business "for him," and then wanders off into a long, rambling, and abusive letter of nearly the same length as his first, heaping up a number of disconnected and obscure statements, but confining his real defence (!) to these words:—"The long "and short of the matter is that, as usual, he "made every blunder that lay open to him, and "grossly deceived me into the bargain, by getting my consent to a pattern lighter than the "one I had first condemned, and then secretly "altering it into one much heavier and in every "respect worse." After this he beats a retreat thus:—"If he has any more to say I shall not "be able to return his fire with the usual velocity, as I am going into the north to-day, "having already lost three weeks of the long "vacation." And with this, away goes this versatile gentleman—this lawyer, clock-maker, bell-hanger, house-decorator—this professor of all the fine arts and many of the coarse—away to hide himself, as well he may, among the mountains of the north for a season.

But before he goes, he gives the dismal bell of Westminster another stroke, telling us that several musicians of great eminence assure him that the new Big Ben is very superior in tone to the old one, which deviated from the pattern he had given. "One of them says he considers "it the finest bell in Europe." This, however, is a matter of musical opinion, which he does not feel competent to discuss himself; but after

all that has been said to the contrary, "by persons not much more competent," it is a fact which ought to be known. Surely we ought to congratulate ourselves on knowing that this gentleman is no longer in a position to vent his nonsense upon us with his "usual velocity." The only thing to be regretted is, that his bell is too big to be taken with him.

Sir Charles Barry's answer to this last effort of his foe is brief enough. Like ourselves, he is "at a loss to discover in Mr. Denison's letter "any 'decisive' or even intelligible reply" to his statements; but is glad to find that he no longer denies having ever seen or had anything to do with the minute hands, which he has now condemned as useless. He (Sir Charles) is content, therefore, to leave the matter as it now stands, and has no wish to intrude further, by making any remarks upon "the gratuitous and "unfounded assertions and insinuations" regarding himself.

On the 26th, Mr. Thomson Hankey, M.P., put a question in the *Times* which we should like to see answered properly. He asks by whose authority Mr. Denison was placed in a position of responsibility in this matter. "I "made the inquiry in the House of Commons," he says, "but I was not able to obtain any "satisfactory answer." He then says, we all know that £20,000 of public money have been spent on this clock. What we have got for our money we do not know, beyond having an ordinary clock of which, after several years, one face alone is made use of, and a bell of no ordinary sound, but better suited to be used for tolling on great solemn occasions than for the ordinary use of a clock-bell.

"But what I want to know is," he continues, "who authorised Mr. Denison to have anything to do with the business? Is Mr. Denison a professional clock-maker, or a sub-contractor who has undertaken the contract which we all understood to have been given to Mr. Dent? Or is he merely an amateur who has been consulted on the occasion by the Chief Commissioner of the Board of Works? If the latter, may we hope that his services may be speedily dispensed with, as I think that we should all feel more safe that the further arrangements connected with this very costly piece of mechanism were intrusted to the management of some professional clockmaker, such as Mr. Dent, who would be really made responsible if the work is found to be to any considerable extent a failure—a failure, at least, in obtaining such a clock and bells as the public have a right to expect for an expenditure of £20,000."

Mr. Denison, in reply, says, "I am superintending this work because I was asked to do "so by the Duke of Somerset, on the recommendation of the Astronomer Royal, in 1851, "and again by Lord Llanover for the bells in "1855, after one of his two predecessors had "tried in vain to get the business managed "otherwise, and the other had neglected it altogether." This answer will do for the present. The question will have its effect, notwithstanding Mr. Denison's evasion.

THE GREAT VICTORIA BRIDGE OVER THE ST. LAWRENCE.*

THE present autumn will witness the completion of, perhaps, the greatest engineering work of our time: of that great bridge across the river St. Lawrence, of which the Britannia Bridge over the Menai Straits proves to have been but the precursor, as to Americans it will hereafter seem but as the shadow. The Canadians, as may well be conceived, are intensely excited at the prospect of finding their country distinguished by so great a work of science; and throughout the United States the completion of the Victoria Bridge is regarded as an important event in the history of that New World which, since its discovery, has been marked by such rapidity of progress.

It may not be uninteresting, at such a time, to

* Communicated.

recall the circumstances under which this work was undertaken, and to record briefly the history of its construction. There are many, indeed, who will gaze with wonder on the lofty piers and the stupendous tubes of this structure, to whom its peculiar features may scarcely suggest themselves; yet the greatness of the conception of this design consists, in reality, less in the size and character of the structure itself than in the objects, political, commercial, and scientific, which it is capable of effecting.

The primary necessity of a new country is a road. The better the line of communication, the more certain the new country of success. The greatest boon, therefore, that could be conferred upon Canada was the construction of a railroad: and those who devised and carried out the project of the Grand Trunk Railway, connecting the different dependencies of the British crown in North America, and passing through the richest parts of both Upper and Lower Canada for a distance of 1,200 miles, must be regarded as great benefactors to the country.

Yet, grand as was the conception of the Canadian Railway, its original design was imperfect. It was not a road through the province alone which Canada required. It needed, imperatively, a facile communication between the north and south shores of the St. Lawrence—railway connexion, free from the inconveniences of transshipment with the United States, and, above all, direct communication with the sea-board of the Atlantic.

A very little consideration of the circumstances of the country will show the imperative character of these requirements. The broad and rapid river St. Lawrence, whilst during the summer months of the year it opens out the whole of Canada to the ocean, for the five winter months completely isolates the province. Canada, lying to the north of the river thus frozen up throughout its course, is itself commercially as well as physically congealed. During that protracted season no ships can leave or can reach Quebec. With the United States the communication is, in every sense, of the most frigid character. Up to a very recent period, even intercommunication between different localities of Canada itself was, during winter, maintained with difficulty. To sleigh for 180 miles, as from Quebec to Montreal, was a task attended with no little trouble and with very considerable cost. Of course the transport of goods was impossible. Commercial markets, therefore, were comparatively useless. In fact, the want of means of communication with the outer world, prevented by the frozen state of the great river boundary and highway of the province, deprived the Canadian of nearly one-half of his active existence.

To the Grand Trunk Railway a direct and uninterrupted communication between the north and south shores of the St. Lawrence was also of vital consequence. Inasmuch as a bridge across the St. Lawrence was the key to the whole province, so, in possession of that key, the Grand Trunk Railway would command the whole external intercourse of Canada; whilst, without it, it must remain a mere provincial line. The tide of immigration sets very much into Canada from and through the United States. The whole of that traffic so important to the Grand Trunk Railway would have been lost without the connecting link between Canada and the United States. In the winter season, also, the Grand Trunk Railway, kept open, despite snow and frost, by various arrangements and appliances, would command the trade of the province without having to contend with any steam-boat competition. To show, by one illustration, the importance of a bridge to the Grand Trunk Railway, it may be mentioned that the Canadian Government contribute the large sum of £50,000 a year to the Steam Ship Company, upon the condition of its opening and maintaining the best direct steam communication between Liverpool and Canada. In the summer months the route can be directed from Quebec; but in the winter that is impossible. Without crossing the St. Lawrence, therefore, the route for

which this handsome subsidy is paid could not be maintained, and the Grand Trunk Railway Company and the Canadian community would alike sacrifice the advantages of direct communication between Canada and Europe.

These considerations naturally weighed with increased strength upon the Canadian people and the directors of the Grand Trunk Railway as that line approached completion. A bridge they saw that they must have; but the question was, could such a bridge be made?

"The rapid river ran deep and wide;"

and there were not a few who thought that to span it by a bridge would be little better than a temptation of Providence.

The difficulties, indeed, of crossing the St. Lawrence were far from inconsiderable. Its width, even at the most available point, is very formidable; its current is very rapid; its depth not insignificant. Besides this, the navigation of the river, not merely by steam-boats and other vessels, but by enormous timber rafts, had to be provided for; so that unusual elevation and unusual width between the piers were both required. There was another obstacle, more formidable—far more formidable—than all. In the winter season the river St. Lawrence presents a field of ice from three to five feet thick. Whilst it is thus frozen, the river rises sometimes as much as twenty feet above its summer level. This rise of water might be provided for; but how was accident to be avoided, at the annually-recurring period when "THE BREAKING UP OF THE ICE" exhibits, in North America, one of the most wonderful operations of nature on that continent?

This "breaking up of the ice" in North America, though welcomed as the harbinger of returning summer, is an event which carries with it no inconsiderable amount of apprehension to the mind of the Canadian. From the extreme thickness of the ice in the middle of the river, little or no effect is immediately produced upon it by the action of the sun. But the banks of the river, imbibing the heat, melt away the thinner portion of the ice which touches them, thereby depriving the main body of the support it receives from its contact with the land. Then, when a small line of blue water intervenes between the shore and the river ice, the ice begins to move, first slowly, then more rapidly, until the velocity and power of the current, rapidly increased by the melting of the snow, wrenches the ice upwards, and breaks and tears it into fragments, which, larger or smaller, go floating down the river in masses, bearing before them almost everything which they encounter.

Dismal tales are rife in Canada of the fatal disasters which have occurred to life and property by "the breaking up of the ice." The city of Montreal has especially suffered from these fatalities. Before now, the ice has burst into that city and been found sliding down its streets. It has broken into the second-floor windows of dwelling-houses after blocking up the front doors for weeks. It has forced down river terraces and spoiled public and private gardens. Large warehouses, erected without due protection on the banks of the river, have been pushed over by the great moving sheets of river ice, as if they were mere houses of cards. At sudden bends of the river, where the ice meets with obstruction, it piles itself sometimes into huge icebergs, from fifty to eighty feet in height. At length, when the river rises, these icebergs get again into its current, and go rolling and sweeping down the St. Lawrence, carrying danger and destruction all before them.

Could any bridge be devised to withstand these formidable difficulties? If possible, how was such a bridge to be constructed? The directors of the Grand Trunk Railway, to whom these questions were so vitally important, took a course which will probably be thought to rebound greatly to their enterprise and sagacity: they determined to take the opinion of the most eminent engineer whose advice and counsel they could obtain.

The Britannia Bridge across the Menai Straits was opened in 1849, and it was not, therefore,

unnatural that in 1852 the directors should look to Mr. Robert Stephenson as the engineer most competent to advise them. Mr. Stephenson considered the subject of so much interest and importance, that he determined to go out to Canada, personally, for the purpose of dealing with it. He accordingly repaired there at the end of the summer of 1853, and, after examining into the facts, made a public declaration of his opinion, that a bridge across the St. Lawrence was practicable. On the 2nd of May following, Mr. Stephenson addressed to the Grand Trunk Railway directors a report, in which he considered the whole question in three branches: first, as to the description of bridge best calculated to prove efficient and permanent; second, as to the proper site; and, thirdly, as to the necessity for such a structure. Upon the first point he did not hesitate at once to recommend the adoption of a tubular bridge, as the description of bridge best fitted for a permanent, safe, and substantial structure in such a situation; on the second point he was not a little influenced by considerations affecting the flow of the river and "those almost irresistible forces" consequent upon the breaking up of the ice in spring.

As Mr. Stephenson's view of the nature of these forces, and the best mode of encountering them, has not yet, that we are aware of, received publicity, it may be interesting to place them upon record—especially as we are enabled to do so with authority. Mr. Stephenson, on his arrival in Canada, met with numerous alarmists, who could graphically describe to him the effect of the ice, but he met with no one who had in any way measured or calculated the amount of its pressure. In considering the question whether a bridge could be constructed to withstand that pressure, it appeared to Mr. Stephenson to be of primary importance to ascertain really and precisely what that pressure was. This was a question of calculation; though, in the absence of any data, the difficulty was how to calculate it. And here, before the reader proceeds further, he may, perhaps, not without advantage, pause for a moment to ponder on the way to solve the problem—what is the amount of the pressure of ice four or five feet thick in a running stream of a certain inclination, velocity, and breadth?

This problem puzzled Mr. Stephenson himself at first; but it was not long before he hit on an expedient. He first got at the inclination of the river; next at its velocity. He then assumed that the ice upon that river was what they told him it usually was, from four to five feet thick. He then inquired into the condition of the river, and he found that, about nine miles above Montreal, there was a fall called the Fall of Lachine, which, of course, separated the body of ice above the fall from the body of ice below it. Taking these data, he calculated what would be the pressure of nine miles of ice, from four to five feet thick, lying on a plane of a given inclination, and pressing against the piers of a bridge across the channel. The result of that calculation in figures it would be unnecessary, even if it were possible, to state; but, whatever were the figures, they enabled Mr. Stephenson at once to realise one all-important fact. He arrived at the conclusion that "the almost irresistible force" of this mass of ice would crush or sweep away any ordinary bridge, and that all the suggestions previously made for encountering the difficulty were only likely to result in disaster if carried into effect.

For up to the period of Mr. Stephenson's Report, great difference of opinion existed in Canada and elsewhere as to the probable effect of the ice pressure. One party held that no bridge whatever could stand against it; another, whilst admitting the difficulty to be formidable, thought timber casings or fenders, such as those in use on the small rivers of Norway and elsewhere, would be an efficient protection for the piers. The proposal most forcibly impressed on Mr. Stephenson was to protect his piers by what is called a "crib-work;" that is to say, by large masses of timber in front of the piers, crossed and weighted, and as

thick or thicker than the ice itself. It was evident, from the first, that this extensive crib-work must be an additional obstacle and impediment to the free navigation of the river, and to the passage of the ice. But, beyond this, Mr. Stephenson's calculations convinced him that such a work would be entirely inadequate to protect such a structure as he contemplated, in such a river as the river St. Lawrence; and that, even if the crib-work stood, it would be subject to such abrasion and wear and tear, from its conflicts with the ice, that it would require to be reinstated at least every two or three years. It was more than doubtful to his mind if such an arrangement would be capable of resisting the ice at all; and if it did not, the capital of the company would be wasted. Mr. Stephenson, therefore, at once determined that such a work was undesirable; and that such enormous stakes as those at issue could not be left dependent upon the uncertainty of such an expedient.

The abstract methods he had taken to ascertain if any bridge would withstand the almost irresistible pressure of the ice, had not alone convinced Mr. Stephenson that no such projects would avail as those proposed in Canada. They had equally satisfied his mind as to the amount of resistance requisite to encounter the pressure against which it was needful to provide. Knowing what timber would not resist, he equally knew what resistance could be afforded by substantial masonry. "Cribb" he felt were useless, but there were methods by which the pressure could be resisted independently of "cribs." Mr. Stephenson decided on the adoption of stone piers, to carry the tubes at wide intervals, each pier having, on the side opposed to the course of the stream, large cut-waters of solid stone work, inclined against the current, up which, as it were, the ice would creep, and break itself to pieces by its own weight and pressure. He arranged that these wedge-shaped cut-waters should present angles to the ice sufficient to separate and fracture it as it rose up upon the piers, but at the same time so obtuse as not to be liable themselves to fracture. These piers, therefore, were devised to answer the double purpose of piers and ice-breakers. They exhibit, as now constructed, every indication of massiveness and power to resist pressure as well as of stability to support the superstructure. Experience, indeed, has proved the piers suited for all the purposes for which they were designed. During the four years the structure has been in progress, it has entirely fulfilled all the conditions its originator anticipated; and it has withstood, in the most satisfactory manner, the most violent pressures which have followed the break-up of the ice.

Whilst the piers of this bridge are thus peculiar in their design, in order to meet the peculiar circumstances of the country and the climate of Canada, the superstructure, which creates in America so much surprise, is an elongated repetition only of the design for the Britannia Bridge. The Victoria Bridge is indeed remarkable for its extreme length, but its several tubes are not so long as those of the Britannia Bridge, and are only otherwise distinguishable inasmuch as that they are the longest tubes yet constructed without the adaptation of the cellular principle. It deserves notice, however, that these tubes, in all their details, were designed, plate by plate and rivet by rivet, in the office of Mr. Stephenson, and were calculated for every strength and strain, and prepared and arranged in all their details under the sole superintendence and supervision of his relative, Mr. George Robert Stephenson. With such nicety were all the arrangements respecting these plates conducted in this country, that, under the directions of that gentleman, every plate and piece of iron was punched in England before it was sent out to Canada; and elaborate and detailed drawings and instructions were sent by the same hand to show the method of connexion. On the arrival, therefore, of each separate cargo of iron in Canada, little remained to those upon the spot but to fasten together the

various pieces, and place them in their order and position as directed.

So entirely, indeed, have the details respecting the tubes been conducted on this side, that it has not only devolved on Mr. G. R. Stephenson to examine the quality of the iron at the iron-works, but to superintend the construction of the plates at the manufactory, and to issue instructions for putting the pieces together. Upon him has devolved the duty of seeing to the shipment of each tube as it was completed, and of signing the certificates for payments, not alone to the contractors but also to the resident engineer and other officials in Canada, who were employed and paid under Mr. Robert Stephenson's directions. It is most gratifying that, from first to last, the design has been carried out harmoniously and efficiently by all concerned. Great credit is due to Alex. M. Ross, who was appointed the resident engineer to superintend the bridge works in Canada, and who has especially devoted himself to the erection of the masonry; to Mr. Hodges, who, from the commencement, has most efficiently and honourably represented Messrs. Peto, Betts, and Brassey, the contractors, and on whom has devolved the principal responsibility in the execution of the works; as well as to Mr. Stockman, who, in the early part of the present year, went to Canada, accompanied by Mr. S. P. Bidder, to make a full inspection and detailed report upon the works—a duty which was performed in a manner eminently calculated to satisfy the minds of the engineers and of the public.

It is not the object of the present preliminary paper to enter into the fuller statement, which will hereafter be given, of the dimensions of the bridge, of its quantities, and of the various details connected with its construction. The present object is rather to exhibit the theory upon which it was commenced and carried forward. One remark, therefore, in conclusion, is alone necessary. Canada owes this bridge to one mind—the mind of Robert Stephenson. Had that eminent engineer expressed the smallest doubt or apprehension, the directors of the Grand Trunk Railway would have shrunk from involving their company in an expenditure of a million and a half of money to carry a bridge across the St. Lawrence. Until Mr. Stephenson had satisfied the Grand Trunk Company, they would not entertain the idea of constructing such a bridge; and, unquestionably, Mr. Stephenson would never have satisfied the company unless he had thoroughly satisfied himself. It was the reliance of the company on Mr. Stephenson's experience and professional reputation that induced them to commence the bridge; and having pledged that experience and reputation, Mr. Stephenson, who would have been responsible for failure, is entitled to the full meed of honour and of fame which must hereafter attach to the successful execution of so great a work. He has indelibly inscribed his name on the structure which resists the ice of the St. Lawrence.

THE ENFIELD RIFLE, PATTERN 1853.

THE Enfield rifle musket of pattern 1853 has not been exactly described as yet, although several high authorities have attempted the task of explaining its peculiarities. In as few words as is consistent with clearness we shall endeavour to supply the deficiency. The stock of this deadly weapon is of walnut wood, imported principally from Italy. Before being manufactured, each particular piece of it is subjected to careful examination by Government Inspectors, who place distinctive marks upon all they accept; consequently, if a stock exhibit defects at a later stage the Inspector who passed it is made responsible for his error. Walnut wood is used because it is at once light, tough, and capable of withstanding great changes of climate. The barrel is of wrought charcoal-iron of the best quality, and is usually supplied by Marshall and Co. of Sheffield. It is required to be prepared in the most scrupulously careful manner. Each barrel must be perfectly solid and

without even the appearance of a seam.—If a crack be discovered even after the finishing work has been given, the barrel is condemned. They are all subjected to two tests during the process of manufacture, once in an early stage, and again when nearly completed, and in each case with charges of gunpowder three times greater than that required for the longest range.

The length of the barrel is 39 inches, the outward diameter at the muzzle $\frac{1}{2}$ inch, and it tapers towards the breech, where, of course, more strength to resist concussion is necessary. As may be supposed, the bore has to be an object of especial care. It must not have upon it the slightest scratch, for if it had, the saltpetre of the gunpowder used subsequently would adhere—more especially in rapid firing—and make the cavity larger. The diameter of the bore is rather more than $\frac{1}{4}$ inch, but less than $\frac{1}{4}$ th, in fact, by the micrometer—decimal, .577, and this must be exact, for the rejecting gauge is only decimal .580, thus allowing a latitude to the worker of less than the 3000th part of an inch. Of the grooves or rifles, of which there are three in each barrel, it may be said that their accuracy of finish is of equal importance with that of the boring. The depth of these grooves at the muzzles does not exceed the 500th part of an inch, whilst the width is $\frac{1}{4}$ ths. The twist or pitch is equal to one half turn in the length of the barrel. The breech end of the latter is chambered to allow for the expansion of the bullet. The bullet, as is perhaps known, is conically shaped, and has its back end recessed for the insertion of a box-wood plug. This plug, driven forward at the first shock of the explosion of the gunpowder, expands the lead until it fills the grooves at the breech. In passing towards the muzzle the bullet is subjected to the compression of the shallower portion of the groove, and hence the force with which it wings its way as a messenger of death! The bayonet is a fitting of the rifle, and in the hands of a British soldier is a formidable instrument, as his enemy has ere now found. The blade of the bayonet in this case is made of the very best cast-steel, finely tempered, and welded to a socket of wrought iron, which is bored out to the precise size of the outer diameter of the muzzle, which therefore it fits. A little contrivance called a locking ring enables one to ship and unship the bayonet easily, but makes it difficult for a foe to do so. It is twisted, as it were, over the fore sight in being fixed, and has to be twisted back in a peculiar way when removed. The back sight is a simple and excellent contrivance. It is composed of a leaf, which works on a joint attached to the "bed," and on this a little slide can be worked at pleasure according to the gauge required. This slide is graduated and figured for regular service, commencing at 200 yards and advancing to 1,000. By raising this slide, therefore, to any figures you please, and bringing a little V-shaped nick in the slide to cut the line of the fore sight, a steady-handed and quick-sighted rifleman may assure a certain range. The back-sight when all its parts are complete, is soldered to the barrel. The lock is a most ingenious and important part of the killing machine, and consists of a number of parts—first, the lock plate: this is of the best wrought iron, case-hardened. Fitted to this, with much nicety, is the tumbler: this latter is of the best cast steel, hardened and tempered to a spring temper. Then there is the sear also of steel, and tempered à la tumbler. The nose of this sear is of a wedge form, and fits into a notch cut in the tumbler. When the rifle is at half-cock, the trigger may be pulled with any amount of force, and the sear cannot be disengaged nor the rifle be discharged. But there is another notch in the tumbler, and when the sear is made to fall into that by placing the rifle at full cock, a pressure of 13 lbs. on the trigger brings down the hammer upon the nipple. Over the tumbler and sear is placed a *bridle*, of wrought-iron, case-hardened, and firmly attached with two steel screws. This is properly named, for it leaves the lock, free for action, or bridle it immovably.

The swivel or link connects the main spring with the tumbler.

The main spring of tempered steel is of much consequence, and has to be most carefully prepared. It is brought to a standard gauge, and is tested in every way for strength and "set." This latter is effected by compressing and expanding it in the most severe manner, and making it "give" finally at a pressure of 14 lbs. The sear spring is used for putting a pressure on the sear, and keeping it up to its work with the tumbler. The hammer is a very peculiarly-shaped piece of work, with a square mortise fitting the squares of the tumbler.

If the hammer was not well fitted its constant action in falling upon the nipple would cause it soon to get out of order. The nose of the hammer is cupped large enough to fall clear of the outward diameter of the percussion cap. The cup or recess must be made extremely smooth and clean, because if at all rough there would inevitably take place within a deposit of saltpetre, and this in action would constantly be augmented until at last it fouled and stopped up the communication hole in the nipple. After the hammer is driven on to its place it is secured by a screw, which is furnished with a head large enough to cover all the jointing. The hammer and screw are both made of case-hardened iron. The nipple is of cast steel, first hardened and then let down to a blue colour. The material of which it is composed must be of the very best quality, or they would, from the treatment to which they are exposed, be continually breaking off. The nipple is attached by means of a very finely-pitched thread—20 to the inch, indeed; it is screwed down to its "shoulder" on the cone seating of the barrel. Perhaps the term "cone" would be a more appropriate name for the nipple. It is conical in outward form, whilst the inside comprises two distinct cones tapering either way from the centre or communication passage. This passage is very small, little larger, in fact, than an ordinary pin would fill. The nipple is coned from the top side to allow the detonating powder, when the cap is exploded, to have free access to the communication passage, and from this it is coned away suddenly to give facility for the flame, after the explosion of the cap, to spread over the charge, and thereby ensure its explosion.

As to the ramrod, it is made of steel very carefully hardened and tempered. It is considerably larger at one end than the other, and has a mortise cut through the stoutest end for the purpose of attaching to it a wiper for "swabbing" out the barrel. The other end has a screw cut upon it for the purpose of fastening thereto a small corkscrew-like mechanical contrivance for drawing the charge if required. There is a small piece of iron let into the stock as a bearing to the end of the ramrod, and likewise to prevent injury to the wood if dropped too heavily into its place. This is the *rod-stop*. There is also connected with this matter a *rod spring*, and this exerts such an amount of pressure on the ramrod as to prevent its falling out when hurriedly used in active service.

The most important component parts of the Enfield rifle have now been spoken of, and some description of what is technically known as the "furniture" branch of its manufacture may next be given. In the first place, then, we have the "nose cap," this is of brass and fixed to the nose or end of the stock by means of a screw. It is intended to give a firmer bearing to the barrel, and to prevent the fracturing of the wood upon which it rests. Then we have the bands which slip over the barrel and stock, and confine the two together. These are each tightened up by a screw; there are three of them, the upper, middle, and lower. They are of wrought-iron, and their forging is a very important piece of work for the smith. They have to be welded up solid, and as they are all afterwards machined, must be forged to a gauge. It requires a very expert fitter to finish these strange-shaped hoops. When finished they are brought down to the blue stage, and then affixed in their respective places. To the upper band is attached a swivel or bracket

for the convenience of the rifleman in slinging the weapon. This, too, is of wrought-iron blued. The trigger is of wrought-iron case-hardened. It is let into what is called the trigger-plate, which is of brass, and a screw passing through them both forms a joint. The trigger is brought into contact with the tang of the sear by the application of a pressure equal to 13 lbs. This releases the tumbler and lets off the hammer on to the cap. To protect the trigger there is contrived a guard made of brass, and affixed over all to the stock by means of two screws and a small round pin. Next we have the butt or heel-piece, also of brass, and fastened by means of three screws to the butt-end of the stock. We must not forget, either, two little side-cups of brass, which are sunk into the stock on the side opposite to the lock, and which afford substantial bearing for the screw-heads which draw the lock into its place and hold it there. These complete the list of components and furniture of the rifle musket of 1853; but it remains to us now to sum up all the items in one catalogue with their technical names. Few, on a cursory glance at the light, polished, handsome weapon which is now coming into such general use among amateur and regular soldiers, would believe that so many as sixty accurately moulded and fitted pieces of steel, brass, wood, and iron went to make it complete, yet such is the fact, and here are the names of these pieces:—The stock, the barrel, the bayonet, breech-pin, locking ring, locking ring screw, ramrod, rod stop, rod spring, rod spring pin, two side cups, nose cap, nose cap screw, two side screws, tang screw, trigger, trigger plate, guard plate, guard pin, three guard screws, butt plate, two butt screws, guard swivel, swivel screw, two lock nuts, upper band, middle band, lower band, three band screws, nipple or cone, tumbler screw, sear screw, sear spring screw, bridle screw, two sight screws, locking ring stop, sight bed, sight leaf, sight spring, sight slide, sight cap, hammer, lock plate, tumbler, sear, sear spring, swivel, bridle, band swivel, and main spring!

When it is known, too, that from the excessive care of the workpeople at the Enfield Small-arms Factory, and the admirable precision with which the various and beautiful machines in use there work, these pieces are all counterparts of each other, and that the components of a hundred rifles may, after being indiscriminately mixed, be taken up and put together without difficulty or delay, it will be admitted that their manufacture has reached something like perfection in England. It is our purpose, however, to endeavour ere long to convey a more exact description of the mechanical appliances in use at Enfield than has been afforded to the public, convinced that our labour in the task will be appreciated.

"THE NAVIES OF THE WORLD."

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—Perhaps I may be allowed to say a few words in reply to the observations contained in your last number, relative to my work on the "Navies of the World."

The reviewer commences by suggesting that the book is little more than a compilation of the contents of the parliamentary returns which appeared at the beginning of the present year; whereas the materials had been in progress of collection for many months, not to say years, previously, and the greater part of the book was actually in type long before any of the parliamentary papers were issued. From them I selected a few tables likely to be useful, throwing them for the most part, however, into the Appendix. But had I obtained earlier access to these documents, they would have been of but little service in the main object I had in view, that of enlightening the English public as to the real strength of the French navy—a topic upon which hardly anything was accurately known, until I printed the only reliable catalogue of French men-of-war now in existence, showing at the same time the power of each individual ship, the date when her keel was

laid down, when she was launched, and, in the case of steamers, the horse-power of her engines, and the name, in most instances, of the engineer by whom they were constructed. When it is remembered that no navy list is allowed to be published in France, that the very meagre accounts to be obtained here and there through private channels were often grossly incorrect, and the information, from whatever quarter procured, had to be repeatedly checked in order that the results should be of any value at all, it seems scarcely fair that one who has toiled as I have done with so important an object in view, and with little prospect of personal emolument, should be classed with the mere literary hack who "gets up" a volume out of a blue-book at the bidding of a publisher. No one, who did not accompany me in all my wanderings, extending as they did over many thousand miles—no one unacquainted with the heavy outlay in a variety of ways, can form any idea of the drudgery I underwent in order to ensure the utmost attainable accuracy, nor of the cost at which it was procured. I am scarcely surprised, therefore, that your critic should affect to treat the matter so lightly; but why should he—speaking of an individual with whose previous studies and pursuits he must necessarily be altogether unacquainted—say, "considering who he is, and how very little he could be expected to know of the world's navies, he has really done his work astonishingly well."

The subject happens to be one with which I have been familiar for nearly five-and-twenty years, not only by study and research, but, to a great extent, by actual observation; and I believe I have in my possession more voluminous documents relating thereto than would, perhaps, be found in the possession of any other private person. Practically, too, though only in the humble capacity of a yachtman, I have had some slight experience in shipbuilding, and in the construction of nine vessels, varying from ten to two hundred and odd tons each, have successfully accomplished in every instance the particular object I had in view, a feat not invariably achieved by our professional shipbuilders, even when aided by the omniscience and boundless resources of the Admiralty. It is, therefore, just possible even for an officer in a rifle regiment—presumptuous though it may seem—to know something of navies and of the true but obscure principles of shipbuilding.

Your reviewer having tested my pages, and fortunately not having been able to detect a blunder "in the detailed lists of our own navy"—nevertheless charges me with errors—"errors into which none but a purely amateur writer could have fallen;" but all he can allege against my accuracy is a statement with reference to the draught of water of some of our larger screw ships, respecting which he says that "no naval man need be told that these are most absurd statements." In justification I may observe that he has, unluckily for his own acumen, pitched upon the *only* assertion in the whole volume for which I am indebted to an English naval officer.

While the proof sheets were passing through the press, my attention was called to an article by an officer in the navy in the October number of the *United Service Magazine*,* giving the draught of our steam men-of-war. I admit that I was somewhat surprised to find them stated as they there appear, but relying upon the high character of the periodical, and the information of the writer, I quoted his words: "The following abstract," says he, "will be found pretty accurate in showing the draught of water in screw ships:—

	Feet.
Screw 3-deckers, as Duke of Wellington	34 to 36
" 2 " as Benown	32 to 35
" " as Brunswick	28 to 33
" blockships, as Blenheim	21 to 23
" frigates, as Orlando	30 to 33
" " as Euryalus	23 to 26
" " as Arrogant	19 to 23
" " as Dauntless	17 to 20
" corvettes, as Highflyer	17 to 20"

The above is my authority—one of the very few, I must admit, which I omitted to verify. The alleged error, if error it should be, is not mine, then, but that of an experienced writer on naval subjects.

The incident is in one respect satisfactory, *since* it shows that your reviewer, with all his practised powers brought to bear upon my book, was notable, out of the many thousand separate facts it contains, to pick out one upon which a reasonable allegation of carelessness or inaccuracy could be based.

For all that, he concludes with a somewhat disparaging remark, observing that the compilation "is useful and timely, that many may read it with profit while no one must believe *all* that it says."

I must now apologise for obtruding myself at this length upon your space. I should not have done so but that, out of two-and-thirty different critiques forwarded to me, yours is the only one which disputes with me that absolute accuracy which I have striven so earnestly to attain, I believe, not altogether unsuccessfully.

I am, Gentlemen,

Your obedient servant,

THE AUTHOR OF "THE NAVIES OF THE WORLD."

United University Club, 30th Aug., 1869.

[By the tone of the above letter Mr. Busk invites us to a species of dispute for which we have no affection. Instead of answering him angrily we will take the trouble to go carefully over his remarks, and notice such of them as seem to need comment. Mr. Busk begins by saying:—"The reviewer commences by suggesting that the book is little more than a compilation of the contents of the parliamentary returns," &c. This is an error. We suggested that the parliamentary returns probably gave rise to the volume; but we never implied that the volume contained "little more" than they. The later portions of our article gave Mr. Busk full credit for a large amount of original matter. We are next told that "the greater part of the book was actually in type long before any of the parliamentary papers were issued." Now, while we are quite willing to accept Mr. Busk's word, we are not willing to let the matter drop without showing some few of the grounds we had for our conclusion. The first parliamentary return of the present year upon this subject was published in February, and appeared in our own Magazine on the 4th of March. At this time, then, Mr. Busk tells us "the greater part of the book was actually in type." Now, we are prepared to show that in *every* chapter there are passages which would lead to a contrary belief. The very first sentence of the *first* chapter speaks of "the secret league into which it is generally believed he [the Emperor Napoleon] has thought proper to enter with Russia." Did not the rumour of the "secret league" first get bruited during the late Italian war? and did that war begin long before February? In the *second* chapter we are told that the "Conversations Lexicon" article had "undoubtedly produced a great sensation throughout Europe," and the chapter consists *solely* of a review of that production. The article was not printed in the *Times* or heard of in England until January; could the European sensation created by it, then, have come to pass, and been written and printed about long before February? In the *third* chapter Mr. Busk quotes copiously from the speech made by Sir John Pakington on the 25th of February last; and gives several extracts from papers published in the following April; could this have been done long before February? The *fourth* chapter relates almost exclusively to foreign navies, and need not, therefore, bear materially upon the present argument; but even in this we find a statement of a personal matter, which was not made public till December last; and could not, therefore, have been in type long before February. The *fifth* chapter contains information

condensed from Mr. Isherwood's "Engineering Precedents for Steam Machinery," as quoted in this Magazine on the 18th of February, the volume itself having only appeared during that month; could this have been in type long before February? In his *sixth* chapter we again meet with copious quotations from the parliamentary papers of April last; could these have been in type long before February? The *seventh* chapter begins by again quoting Sir John Pakington's speech of the 25th of February, and then enters upon an elaborate discussion of the Royal Commissioners' Report on Manning the Navy, which was not published till the 19th of February; could all this have been in type long before February? The *eighth* chapter contains quotations from the speech of the Secretary-at-War on the 4th of March last, and others from Sir William Armstrong's speech of the 16th of May; could these have been in type long before February? In the *ninth* chapter we have a long quotation from the *Saturday Review* of the 12th of March last, and an abstract of a parliamentary paper of the 4th of April; could these have been in type long before February? The *tenth* chapter is the last, and is headed "Conclusion;" was this in type long before February? Surely, after all this, we may be excused for not having of ourselves discovered that "the greater part of the book" was written long ago. Mr. Busk next mentions at some length the labours he has performed in acquiring intelligence in reference to the French navy. As we filled nearly a column and a half of our last Number with his remarks on this subject, and as we took pains to state that "he had amassed an unexampled amount of information relative to the French navies and naval ports," we scarcely understand why he has requested us to give insertion to another long statement upon the subject. Mr. Busk next affects to consider our remark about the little he could be expected to know of the world's navies an improper one. This is all very well in its way, but we really must insist upon the perfect right we had to make the remark, especially when it was only made with the view of reflecting greater credit upon him. Does Mr. Busk wish us to understand that barristers generally are well up in naval matters, and must be expected to know much of the world's navies? We think not; we rather suspect he wished to make known what he had done in the way of amateur shipbuilding, and chose this means of telling us. It is more nonsense to talk about the "presumption" of a rifleman knowing something of navies and of the principles of shipbuilding. We used no such language. We must further tell Mr. Busk he is quite mistaken in supposing that we "tested" his pages, and were "not able out of the many thousand facts it contains, to pick out one upon which a reasonable allegation of carelessness or inaccuracy could be based." As Mr. Busk challenges us to speak more fully on this point, we will state what we did do by way of preparation for noticing his work. We first glanced through it in a general way for about half an-hour, which was quite sufficient to show us that it was in the main a mere compilation, and that we had met with a very large portion of it before in various forms, and had, indeed, published much of it in our own columns. We also observed that the subjects discussed in it were very numerous, and were in many instances dealt with superficially. We then turned to the classified lists of our own navy, and found that on the whole they had been gone over carefully; although not so as altogether to avoid errors, for both the London and the Lion appear in his list of sailing ships. It was while looking over these lists that our eye fell upon the extraordinary statement respecting the draughts of water of our larger ships. Mr. Busk now accounts for this statement by saying he got it from the *United Service Magazine*, and sneers at our acumen because a naval man first made it. But it really does not matter where Mr. Busk got it from. That he obtained it in the manner he did only confirms our worst fear, viz., that he has picked up

some few of his facts from sources which turn out not to be reliable, not knowing himself whether they were accurate or otherwise. In his last sentence Mr. Busk still asks to be considered absolutely accurate; and seems to think that line-of-battle-ships ought to draw 36 feet of water because one-and-thirty critics do not know to the contrary! We really cannot oblige him; and as for the one-and-thirty critics—what on earth do critics know of such things? If Mr. Busk had said a schooner drew 36 feet of water he would have escaped the general run of critics with equal impunity. In conclusion, let us say we think the author might fairly have read our article contentedly. We endeavoured to do full justice to his labours; and when we gave him credit for his arduous and successful inquiries into the condition of foreign navies—particularly the French—and stated that his detailed lists of our own navy are also very copious, complete, and accurate, we set a higher value upon his volume than a score of such letters as the above could secure for it. If he makes a wise use of our remarks he will get more good out of them than even thirty-one indiscriminate eulogies will yield.—Eds. M. M.]

THE ATLANTIC CABLE.

THE following report of Mr. F. C. Webb, C. E., has just been made to the Chairman and Directors of the Atlantic Telegraph Company:—

"Valencia, Aug. 10. Gentlemen,—According to your request I made from Valencia a careful examination of the electrical state of the Atlantic cable. I made some tests for comparison on the various pieces of Atlantic cable in Messrs. Glass's premises at Greenwich during July 31 and August 1. I arrived here on the 4th inst., and, assisted by Mr. Collett, made experiments during the 5th, 6th, 8th, and 9th inst. I find the lowest resistance shown to be 278 statute miles. I find it is possible to increase this resistance up to 589 miles by sending a copper current for some time from six 12-plate Daniel's batteries. By experiments I have made on various kinds of constructed faults I find that a fault which could be thus oxidized so as to give (by reversal of the current) a difference of resistance equal to the difference obtainable on the cable—viz., 311 miles, must give a minimum resistance of about 16 miles. When the fault is large, and thus gives little resistance, no great change can be obtained by reversing the battery: and, indeed, it is evident that when the connection between the line and earth is increased beyond a certain extent of surface no difference in the resistance of the circuit can be obtained by reversing the battery. When the fault is very minute it can be almost perfectly sealed up by a copper current, but the resistance will still be very great, even with a zinc current. My experiments show that a fault of about 16 miles minimum resistance can be varied with certainty by reversal of the battery to the same degree as the fault in the cable, and that if the fault gives less resistance than 16 miles it cannot be varied to that extent, while, if it gives more resistance, the variation cannot be produced with the same certainty, nor quite to the same degree. Taking, therefore, the resistance of the fault and cable beyond the fault to be equal to 15 miles, this would bring the fault to about 263 statute miles from Valencia. As I have no information of the return current due to different lengths of the Atlantic cable, which might have been observed and tabulated during the paying out of the cable, it is impossible to check the resistance tests accurately by the observed return current. Comparing it, however, with the return current on the Cagliari and Malta and Corfu cables, and making, roughly, allowance for the increased size of the gutta-pescha in the Atlantic cable, I find it to be about what is due to the supposed distance of the fault. I also made experiments on the return current with a wire leading to earth from the cable, and by placing resistance in circuit in this wire I could represent a fault close at hand and of varying resistance.

I found that in such an arrangement, when the artificial fault gave a resistance of 300 miles, the return current was only reduced about 22 per cent. If the real fault, therefore, was close at hand, the return current of the whole length of perfect cable beyond the fault would be only reduced about 22 per cent. also. I am of opinion that the observed return current is much less than 78 per cent. of the return current due to the whole cable, as it would be if the fault were close at hand and of a resistance of about 300 miles, and that it coincides, as nearly as I can judge, with that due to the length shown by the resistance. Again, when the artificial fault was made to represent a resistance of 260 miles and then increased to 580 the return current only increased about 17 per cent., whereas when the real fault is increased to the same amount of resistance (by sending a copper current for some time) the return current increases about 80 per cent. This shows also that the return current is more influenced by the partial healing of the fault than it would be if the fault was a small one near at hand, and consequently tends also to confirm the supposition that the fault is distant, and offers, when at its *minimum*, little resistance. I am of opinion, therefore, that a serious fault exists about 263 statute miles from Valencia, measured along the cable, and that the cable between that spot and this shore is comparatively perfect. No tests from here can now decide whether the cable is mechanically severed, since all attempts to detect the reception of the most intense currents from the opposite shore have long since proved fruitless. Still, from the various circumstances attendant on the decline of the insulation, there is every reason to believe that the continuity both of the cable and the conductor is perfect. Whether any other faults exist beyond the one alluded to it is impossible to ascertain by tests from Valencia. The fact that the signals received at Valencia were always better than those received at Newfoundland proves, undoubtedly, that the worst insulation has always been near Valencia; and, therefore, it seems probable that if the fault which exists on this coast, and which, very likely, forms the principal cause of leakage, could be removed, the insulation would be so far improved as to render the cable again available for signalling, provided the fault which is said (by those who have tested from Newfoundland) to exist in Trinity Bay was also repaired. I have the honour to be, Gentlemen, your obedient servant, F. C. WEBB."

IMPROVEMENT IN MILL-BANDS.

THE mill-owner and machinist have just been presented with a very great boon in the production of a new fabric for endless bands. These mill-bands are composed of a series of layers of canvas cemented together with the patent vegetable leather compound of Messrs. Spill. It can be fabricated to any thickness; from one to 20 strands if necessary, and in length up to 200 feet by four feet six inches wide. Hence the machinists will have the advantage of cutting their own bands to any length or width without joins, and of uniform strength throughout, at less than half the price of leather, compared with which it is considerably tougher. It will, moreover, stand the action of the atmosphere without change, is not affected by heat under 200° Fahrenheit, or by grease, alkali, or moisture. In fact, it may be used for turning wheels under water if required. It is also particularly applicable to carding engines, as it does not absorb oil, which is a great defect in leather, the wool-carders complaining of the leather becoming soddened with oil after a day or two's use, and then the leather "mats" the wool upon its surface and carries it round, clogging and accumulating the whole of the time, instead of delivering it to the other parts of the machinery as desired. The production has been severely tested, and the orders already on hand at the Government contract works, Stepney Green, have necessitated the erection of distinct and extensive apparatus for its manufacture by the Messrs. Spill, its patentees.

MIDDLETON'S PUNCHING AND SHEARING MACHINES.

MIDDLETON'S PUNCHING AND SHEARING MACHINES.

WE have much pleasure in describing and illustrating one of the useful punching and shearing machines of Mr. W. Middleton. The engraving shows a perspective view of the same. The rise and fall of the cutting and punching block *A* is managed in the ordinary way, the edges being V-formed, and fitted with adjustable slides; the main shaft is made strong enough to take the strain without any perceptible effect from torsion. The spur-wheel *B* is shrouded, as well as the pinion, which is a great advantage in machines used for heavy rough work. The counter-spindle runs through to the front of the frame, and is fitted with a tight and loose pulley *C* and *D*, and a heavy fly wheel *E*, to secure momentum. The screws to hold the cushion *F* on which the punching is effected are tilted down so that their ends rest upon the cone, and it is in this manner that it is kept steady, and has no tendency to rise. The shearing plates *G G*, are not, as in ordinary machines, parallel to the line of the face of the press, but skewed in a slight degree, as will be seen on reference to the engraving. By this means any length can be cut off of bar-iron, and still the shears remain in the proper position for cutting down iron-plate lengthways.

These machines are made of four different sizes, the largest being of strength to punch 1-in. holes through 1-in. plates. Combining as they do the latest improvements it is not surprising that these presses are having an extensive sale. We understand that they were used by Messrs. Fox, Henderson, and Co., and that they have been already supplied to a great many of our leading manufacturers, including Messrs. James Watt and Co., Messrs. Brown, Marshall, and Co., the Messrs. Fowler, and others, giving in every case perfect satisfaction.

CAPT. NORTON'S ORDNANCE RIFLE BOLT.

THE central projecting part of each wing works in and against the bottom of the grooves; the other portion works against the edges of the grooves, and on the face of the lands, so that the projectile works and rests entirely on wood. The bore of even brass rifled cannon cannot be injured by using these projectiles, which may be of ordinary cast-iron. Additional security on this point is also gained by coating the shot with paper in the same manner as my paper-coated rifle shot described in a former number of the *MECHANICS' MAGAZINE*. A few days ago I fired one of these elongated iron bolts into a chalk butt in the Rosherville Gardens, from the four-grooved one-pounder rifled brass cannon from which about twenty years ago I successfully tested my *elongated* percussion rifle shells at Woolwich, in presence of a large number of naval and military officers, with perfect success; of which number the late General Viscount Hardinge was one, and who, being a *clear-headed* man and a zealous officer, wrote to me a few days after, congratulating me on the success of my experiments, adding that they would lead to the most useful and valuable results. Specimens of these shot are to be seen at the Crystal Palace, South Kensington Museum, the United Service Institution, and the grounds of the Victoria Rifle Corps, Kilburn. J. NORTON.

TASKER'S PATENT IMPROVEMENTS IN PLOUGHS.

TASKER'S PATENT IMPROVEMENTS IN PLOUGHS.

MR. WILLIAM TASKER, of the Waterloo Iron-works, near Andover, has obtained a patent for an invention which relates to a peculiar construction and arrangement of the parts of ploughs, known as fixed-headed ploughs, in connection with the front end of the beam and head gear, whereby the plough may be turned at the headlands without having to be carried round by the ploughman. Fig. 1 of the annexed engravings represents a side elevation of a plough fitted with his improvements; Fig. 2 is a corresponding plan of the same, and Fig. 3 is a front view of the plough head. *A* is the plough beam, the front end of which is made round, and fits into the corresponding tube or hollow cylinder *B*, cast in one piece with the vertical frame *C*, and fitting loosely upon the rounded front portion of the plough beam, so as to be capable of turning freely thereon. The collar and pin at *D* serve to keep the end of the beam from slipping out of its place. A flange, *E*, is cast upon the back end of the tube *B*, which fits against a similar collar *F*, fast on the beam itself. These two collars are notched so as to receive the weighted fork lever or catch *G*, which plays freely in holes made in the casting, and is retained therein by cottars. When this catch is dropped into the corresponding notches in the two flanges or collars, the plough beam will be locked or prevented from turning in its tubular socket; but when the catch is elevated out of the notches, which may be effected by the ploughman pulling the chain or cord *H*, or by any other simple contrivance, the beam will be unlocked, and may then be turned over to one side so as to bring one of the handles *I I* on to the ground, and consequently raise the ploughshare, in which position the whole may be readily turned at the headlands. A skid or other convenient rest may be bolted on to one of the handles for the purpose of supporting them when on the ground. The headland being turned, the ploughman re-adjusts the beam, when the weighted catch *G* drops into the notches in the respective flanges *E*, *F*, and

locks the beam in its proper position for work. *J J* are adjustable stumps for carrying the running wheels *K K*; these stumps pass through the overhanging lugs *L L*, formed at the top and bottom of each of the round sockets *N N* (one of which is shown in section in Fig. 3), of the cast-iron frame *C*, and are free to turn therein, thereby enabling the stump of each wheel to swivel or lock round when turning the plough, as shown by the dotted lines in Fig. 2. *O, O* are two bars rigidly fixed to the lower ends of the spindles *M*, and connected at their front ends by a cross bar *P*, which is provided with a number of holes for the purpose of regulating the line of draught, as will be clearly understood on referring to the drawings.

LAYING-OFF: *Erratum*.—In the italic heading, second column, page 135 of our last Number, the word "stern" was omitted by the printer. It should have read "New Mode of Laying Off Cantled Stern Timbers." The omission of the word will not have misled those who studied the article.

SIR HOWARD DOUGLAS'S IMPROVEMENTS ON THE SCREW PROPELLER.

THE *Times* of Saturday last contains a long article on the above subject. After advertizing to the recent trials on board the *Doris*, and mentioning the result which was obtained, and which is so favourable to Sir Howard's views (as explained in a leading article of ours on the 17th of June last), the writer of the article proceeds as follows:—"This (the result of the *Doris* trials) was a great victory for Sir Howard's principles, and accordingly he received congratulations from all but the Admiralty, which alone made no sign. Upon this, after a decent lapse of time, Sir Howard wrote to the Admiralty at Somerset-house, pointing out how he was the originator of the improvement, and how he had himself directed their attention to the subject, and so induced the trials with his screw which had terminated so satisfactorily. He expressed himself delighted that his improvement had proved of such value and importance, and the only reward he wished for or would ever take was the free and just acknowledgment that to him, and him alone, was due the merit of what we may almost term the discovery. After a time, the Admiralty replied most blandly. They were delighted to forward him an abstract of the experiments made on board Her Majesty's ship *Doris*, and would be the last to attempt to rob Sir Howard of any credit which he thought due to his improvements. In the present instance, they intimated that there was but little chance of doing so unfair an act, inasmuch as Sir Howard's improvements of 1858 had been tried previously by the Admiralty on board Her Majesty's yacht *Fairy* in 1853. Now, this latter assertion is very far from being correct. The trials made on board the *Fairy* six years ago were with screws of a peculiar form, cut down into any or almost no form whatever. The screws, too, were utterly different in principle and pitch from the Admiralty screw which Sir Howard proposed to improve, while the trials themselves may be regarded as conspicuous failures, inasmuch as they resulted in nothing, and left the old fan-shaped Admiralty screw precisely as it was

and as it has remained till the present improvement of Sir Howard. The gallant veteran has replied to the Admiralty, calmly persisting in his claim to the merit of having originated the improvement, and hinting strongly that the attempt of the authorities to refer back the improvement to the meaningless trials of 1853 with totally different screws looks very like trying to rob him of the honour due to his skill and perseverance in having been the first to see and the first to work out this important modification of the screw propeller principle. So the matter remains at present. Whether the Admiralty will eventually give the merit where the merit is due we know not; but in the cause of truth, and in the cause of all our earnest, thoughtful men, who so wearily and nearly always so thanklessly labour to promote the efficiency of both services, it is right that the truth should be known, and that the merit of introducing this most important improvement in the form of the screw propeller belongs to General Sir Howard Douglas, and to him alone.

"While we are upon the subject of Sir Howard Douglas's improvement of the screw we may refer to one which, though very simple, is hardly less important in degree than that we have mentioned, and one which it is certain the Admiralty must gladly adopt. We mean, of course, that improvement which is to prevent a ship's screw being fouled by rigging or hardware. In the last great naval war with France our victories were as much gained by the skill with which we out-maneuvred our adversaries as from any other cause. This led the French to prefer always firing at the spars and rigging, while as constantly the English aimed at the hull. These have become the traditional modes of attack with both navies, and the result to be achieved by firing at the rigging now would be almost identical with what was accomplished when ships manœuvred under sail alone. A screw-liner having a mast shot away would now have her screw fouled by the wreck of the rigging drifting into her wake astern within three minutes after the spar fell over. The greater the "way" on the vessel the more certainly would such an accident occur, and in a naval engagement with a mast shot away, and her screw jammed, any vessel would be so completely at the mercy of her antagonist that further resistance would be hopeless. There are many, and some most fatal instances, already on record of the hopeless condition to which a screw vessel is reduced when once her propeller is fouled. Look at the loss of the Prince. Yet in the whole of Her Majesty's navy not a single vessel is provided with any appliance to ward off this most obvious and most serious disaster. In Sir Howard Douglas's improved form of screw the curved edges have, besides the advantage of readily throwing off any floating materials that may come in contact with them, that of not being so liable to be broken by their oblique collision with large spars. The angular parts of the common screw are far more likely to be hitched by ropes than the rounded extremities of the form which Sir Howard has now, we hope, introduced to the navy. These curved edges, he also suggests, should be fitted with sharp gun or other hard metal edges, so that as the screw revolved in the water its power would divide any rope or spar like a powerful circular saw. But his main recommendation as a remedy for this great evil is a contrivance that will enable the propeller to clear itself of any floating wreck of rigging which may hitch upon the screw in its rotation, and which, being drawn down to the root of the blade, would be wound up on the boss so tightly as to disable the propeller or break the screw-shaft, if the engines were not instantly stopped. For this manner of clearing the screw Sir Howard proposes to employ powerful and sharp knife-edges, firmly fixed to the metal trunk in which the screw works, and close to both edges of the blade, in such a manner that any rope that may have hitched on the boss would be acted upon during the revolution of the screw as a body revolving in a turning lathe is acted

upon by a chisel. Thus, revolving with a force derived from the power of the engines, the rope must be drawn into and along the knife-edges, causing them to exert a drawing out sufficient to sever any rope, whatever its strength or thickness, and so clear the screw at once of what would otherwise be the most dangerous and perhaps fatal entanglements. This simple but most efficacious plan we trust soon to see generally introduced into both the Royal and merchant navies, and hope that the Admiralty will make no attempt to purloin the merit of originating this idea as well as that of the form of the screw. How can any inventor look for success at the Admiralty when even Sir Howard Douglas, with all his claims upon the consideration of the authorities, cannot get them to acknowledge gracefully that the improvement they got for nothing is an important one, and is his?"

WILL THE GREAT EASTERN ROLL?

THIS question is discussed by a gentleman signing himself "Vates ante Factum" in the following manner:—

The leading characteristic of the Great Eastern—that in which she differs from every other ship hitherto constructed—is, he very correctly says, that she shall under no circumstances be compelled to lie to, nor in any way to diverge from her direct great circle course. She is to sail exclusively a great circle course, and is not to have recourse to any of those dodges which are resorted to to ~~come a ship~~ under stress of weather. Her dimensions are (so he says) based upon certain calculations of the late Dr. Scoresby, which assigned 680 feet as the extreme length between the crests of two waves, with an average depth in the intervening trough of 60 feet, or a mean elevation and depression of 30 feet each way above and below the level of the ocean at rest. He does not wish to impugn the Rev. Doctor's experience, but, adopting his method of calculation, as detailed in an early number of *Household Words*, he (the present writer) once measured 800 feet between the crests, when lying to in the Collins steamer *Baltic*, in which measurement he was confirmed by Captain Comstock; and he rather thinks that Captain Harrison himself was in command of the *Africa* when she, starting from Liverpool three days after, experienced the same gale on the 11th of October, 1854. Now, supposing that on her voyage out to Portland (which implies on an average a W.S.W. course), she happens to be struck by a gale from due north, it is obvious, says this writer, that, if the Great Eastern is rigorously kept to her course, the trough of 680 feet wide, over which she is suspended, will not be spanned by even her great length, inasmuch as she crosses it diagonally. "Now, I contend," as the wave catches her beneath the quarter, where, from her great sharpness forward, she is rather inclined to be lean, she must roll, and, having no keel, it will be a very severe roll—not in the remotest degree dangerous, but still quite enough to discompose a landsman." In the second place, supposing she is running before a heavy gale of wind, it is equally manifest, says this gentleman, that a modification of the foregoing will take place, the difference being that, instead of rolling, there must be what is technically called a "scending" motion, with the certainty, in case of a short sea, of a very severe shock to the sternpost, though her great strength renders this comparatively unimportant. Supposing, thirdly, that, still sailing from Holyhead for Portland, immediately after rounding Malin Head or Cape Clear, she should happen to encounter a westerly gale, which is likely for the time it lasts to knock up quite as high a sea as any other, the sea will catch her, he says, on the starboard bow, while her stern is still descending into the trough. As, however, she will be advancing at a rate of about 10 knots, she will burst through the wave, quite motionless, it is true, riding majestically enough from wave to wave. As, however, the waves will pass her with their own velocity of about 30 miles an hour, *plus* her speed of 12 miles an hour, in all

42 miles an hour, there will be a tolerable lash of spray. When a ship is lying to in a heavy sea, a little dexterous manipulation of the wheel will keep her comparatively dry. Let her fall off but a single point, and, even though she has bare steerage way on her, stand by for a green sea. Such was the case with the *America* when she had to put back some three years ago. The height out of water of the Great Eastern, and the concavity of her upper lines forward, will prevent her taking a sea on board, but she will be covered with spray forward as far nearly as the paddlebox. The peculiarity of build already noted in her bottom will prevent her being turned, in the event of any sudden emergency, such as she is likely to meet among the coral reefs of the Eastern seas, or the crowded water highways of our own scagirt isle, except at an expense of stewards' crockery painful to contemplate.

Such are the views of this writer, and although they contain little that is new, they may serve to prevent some few individuals from entertaining absurd notions about stillness in a sea-way. We must say, however, in the above remarks the case is put rather more strongly than it need be. The steadiness of the Great Eastern will doubtless be unparalleled.

LUNGLEY'S STEERING-SIGNAL APPARATUS.

THIS simple but most ingenious invention, as applied to the Great Eastern, is due to Mr. Lungley, the shipbuilder of Deptford. By means of this Captain Harrison, or the officer of the watch on the bridge, will be enabled to steer the ship by a signal indicator with as much certainty as if he guided the wheel himself. A small illuminated dial, with a moveable index, is fixed on the bridge, in front of the officer of the watch, and connected with another of the same description in front of the men at the helm. Moving the index finger of the machine on the bridge to port or starboard moves the index of the machine before the helm at the same time, so that not a second is lost in putting the helm hard up or down. In the same manner the rudder itself is connected with another small dial before the helmsmen, which tells by its index that they have exactly obeyed orders, while this again communicating with a similar machine on the bridge shows the officer of the watch the instant his commands are executed. The movements of the latter dial being, of course, regulated by those of the rudder the officer on duty has always the helm, as it were, under his eye, and can detect if the men suffer the vessel to deviate a quarter of a point from her course even for a second. The apparatus, moreover, possesses another advantage, and that is, that simply moving over the index finger to hard a-port opens up two red lights on the port side, and by turning it to starboard a double green one is similarly displayed. Thus small vessels are afforded every facility for getting out of the monster's way in her impetuous rush over the deep.—*Times*.

A SMALL STEEL STEAMER.

THE screw steamer *Little Lucy*, that was lately built for river service in the Brazils, deserves especial notice in having so successfully accomplished the passage from this country to Bahia. She was 70 feet long, 12 feet broad, and 6½ feet deep, and only measured 20 tons register; and on account of the smallness of her size, it was originally intended to have her sent from this country in loose plates, which were to have been put together, and rendered fit for service on arrival at her destination; but to expedite matters it was afterwards determined to rivet her up completely, and send her over under sail and steam to South America. She was schooner-rigged, and although so miniature a craft in her appearance and proportions for so long and precarious a voyage, there was no lack of applications on all sides from captains to navigate the vessel, so satisfied was every one that she would prove a good and safe sea-boat; however, to make sure of her meriting the opinion that had

been formed of her as regards these qualities, it was decided to send her round to Falmouth from the Tees, before she took her final departure from England, and the very severe weather she so successfully encountered on her passage round the coast, left no doubt of her performing the voyage across the Atlantic in perfect safety. Her subsequent safe arrival at Bahia fully justified the anticipations that had been previously formed of her. The material used in her construction was that known as the "Mersey Puddled Steel," and taking into consideration the smallness of the vessel's dimensions, and the thickness of the plates that composed her hull being only one-eighth of an inch, the success of the design and construction of the little vessel must be looked at upon the whole as remarkable, and proves the adaptability of puddled steel for shipbuilding purposes. The Little Lucy was built by Richardson, Duck, and Co., of Stockton, from the designs and under the superintendence of Mr. Herbert L. Thompson, naval architect, in connection with the firm of Messrs. Alfred Brett and Co., of 150 Leadenhall-street.

WRECK OF THE ALMA.

An article in our impression of last week, headed "Boat-lowering Apparatus" (written before the details of the wreck of the Alma and the loss of life that accompanied it had been given to the public), made just comment on the neglect, by owners and officers in charge of ships, of the observance of those proper and necessary precautions for the preservation of life which, in the event of accident, or at times of sudden emergency, might so materially mitigate the disasters that otherwise ensue. We even went so far as to express a hope that the time might come when captains should be put upon their trials for manslaughter should either seaman or passenger be lost from any such cause. This particular case of the Alma shows how absolutely necessary it is for the public safety that some such rule should obtain. "More than twenty persons perished from the neglect of the most ordinary precautions," says the *Times*, in a subsequent leading article on the catastrophe—in which, moreover, it has some admirable comments on the wanton neglect that led to it. Surely the strong and repeated comments of the press must eventually rouse the constituted authorities to enforce more rigidly the legal enactments which are now unhappily almost entirely disregarded, though specially framed with a view to the protection of life at sea. We refer more particularly to "Passenger Act," 1855, clause 27, 18 and 19 Vic., cap. 119; and circular No. 51, 1st Jan., 1857, "Board of Trade." While these are allowed to remain "dead letters," no wonder we have such sad histories as the Alma's to make comment on.

Law Case.

CROWN COURT. — LIVERPOOL, August 27, 1859.
(Before Mr. Baron Watson.)

MACNEE v. NIMMO.

This was an action for the infringement of a patent for making a manufacture called "Zebras." This was a new trial of the same cause.

Mr. Monk, Q.C., Mr. Hindmarsh, and Mr. Ovens appeared for the plaintiff; and Mr. Manisty, Q.C., and Mr. Jones for the defendant.

The patent claimed by the plaintiff was in a twilled or plain fabric backed so as to make it of soft or spongy texture, and printed in shawl patterns to imitate a manufacture called "Zebras," for the Eastern market. The alleged infringement was the making of a figured fabric with raised figures, upon which a shawl pattern was printed, the raised pattern giving the fabric a soft and spongy texture. This was said to be in reality the plaintiff's patent and a mere colourable evasion of it.

The case was not concluded at the rising of the Court, and was adjourned till Monday.

NOTICES.

FAIRPLAY, *Shewness*.—As your letter on the New Works Department of the Admiralty, whether published with or without your name, would have but exceedingly little weight; as, moreover, it is written in a very improper and unbecoming tone; and as, finally, we have confidence in saying that your superior officers, on whose behalf it was written, would be greatly disgusted by its appearance, we cannot consent to publish it.

R. S.—W. P. Le Neve Forster, Secretary of the Society of Arts, in his recent paper on aluminium, gave its specific gravity as 2.6. If this is not sufficiently exact for you, you had better apply to Mr. Foster, who would doubtless furnish you with what you require.

The *MECHANICS' MAGAZINE* will be sent free by post to all subscribers of £1 ls. 8d., annually, payable in advance. Post Office Orders to be made payable to R. A. Brooman, at the Post Office, Fleet Street, London, E.C.

TO ADVERTISERS.

All Advertisements occupying less than half-a-column are charged at the rate of 5d. per line for any number of insertions less than 13; for 13 insertions, 4d. per line; and for 52 insertions, 3d. per line.

Each line consists of 10 words, the first line counting as two. Wood-cuts are charged at the same rate as type for the space occupied.

Special Arrangements for larger or Serial Advertisements. To ensure insertion, Advertisements must reach the Office by 5 o'clock on Thursday evening each week. None can be received after that time for the ensuing number.

The demand for Mr. E. J. REED's paper—

ON THE MODIFICATIONS WHICH THE SHIPS OF THE ROYAL NAVY HAVE UNDERGONE DURING THE PRESENT CENTURY, IN RESPECT OF DIMENSIONS, FORM, MEANS OF PROPULSION, AND POWER OF ATTACK AND DEFENCE,"

has been so great that the *Journal of the Society of Arts*, the *MECHANICS' MAGAZINE*, and all other Scientific Journals in which it appeared in December last, are now out of print. The demand still continuing, it has been deemed desirable to reprint it in a separate form. An 8vo. edition of it, in large type, and on fine paper, has, therefore, been prepared, and may now be had at the Office of this Magazine, price 1s.

Our Weekly Gossip.

We take the following remarks on Sir William Armstrong's career from a speech made a short time since at Newcastle by Mr. Glynn, a solicitor of that town:—"Sir William Armstrong began his life as a useful and valuable member of the profession to which I have the honour to belong, and it was in that capacity that I first knew him. I venture to say to you, from personal knowledge, that the career which Sir William Armstrong was then pursuing was as industriously followed, as closely pursued, and as usefully carried out as that by which his name will be more generally known, and that as the attorney-at-law and solicitor in the High Court of Chancery, Sir William Armstrong was equally distinguished as he is, as not only one of the greatest of the civil but also of the military engineers of this country. When Sir William Armstrong left the profession and ceased that relationship which gave me the right to term him a brother in law, the law society, of which I am vice-president, presented him with an address; and I believe that that kindly recollection of old times and of intimate and friendly association was as grateful to the heart of Sir William Armstrong as any honours that he has received at the hands of his sovereign, or at the hands of his country. Sir William Armstrong commenced life with a very great advantage over other men. He had for his father a very eminent mathematician—a man whose profound knowledge of mathematics, although it never came prominently before the world, must have had a great effect in imbuing Sir William Armstrong with those logical methods of reasoning, and with that extreme exactness which he has carried into his future career. And I have no doubt that as Robert Stephenson owed to the careful teaching of his father in his younger days an amount of knowledge which he never otherwise would have had, and which has made him—a man of high intellect, doubtless, but still not of commanding or overpowering genius—one of the first men of the age, I have no doubt that Sir William Armstrong owed to the mathematical knowledge of his father the groundwork of that science which has since made him so famous."

A correspondent sends the following "Note on a Patent":—"When I was a boy, some thirty years since, (unfortunately) one of my favourite pastimes was to get on board the boats moored in the river of my native town at high tide, and rock in them if not disturbed by the owners. One morning, on going with some schoolfellows down to the river for that object, we made a discovery that rather astonished us, and which engrossed all our attention, for there, moored to a raft of barks, was a boat that threw all the others into the shade. This boat was about the depth of the others, but only half the width, or nearly so, and about twice the length—was beautifully painted and cushioned, and went without oars! This was effected by a pair of *paddle-wheels* fitted to the sides with crank-handles, which could be used together or separate, and the steering could be done by the foot or an inclination of the body. Now, as a boat was my hobby, I always looked forward to the having one (it has not come yet), and determined that it should be like this, because of the ease with which it could be set in motion and the comfort of seeing everything before you. This boat belonged to a gentleman who was largely engaged in the timber trade. Well, Sir, your last number containing a patent for a similar thing, astonished me nearly as much as the first sight of my favourite boat.—ROBT. ESSERT."

Arrangements have been made during the present week for taking the Great Eastern down the river to-morrow morning. At 6 A.M. she is intended to leave her moorings. Four powerful tugs will take charge of her—two ahead and two astern. The latter are to help the gigantic vessel to turn in the sharp angles of the river just between Greenwich Hospital and Blackwall. The Great Eastern herself will also be under steam in her paddle engines, which, if occasion requires, can be turned round to assist the tugs. From Gravesend to the Nore the aid of the tugs will be merely nominal, if used at all. At the Nore two or three days will probably be consumed in adjusting compasses and filling in with coal. The latter will bring her down to a fair sea-going trim—that is to say, a little over 10 feet deeper in the water than she now appears. The slightest possible addition has been made to her draught of water before the Nore is reached. From the Nore she proceeds under easy steam to Portland, and receives her passengers for the first trial trip, returning afterwards to Holyhead, from which harbour she starts on her real trial trip to Canada on or about the 15th.

Captain Norton requests that the following may be inserted:—"Gentlemen,—There was a slight error of the heading of my letter in your Magazine of yesterday. The heading should be properly, *Muzzle-loading Sporting Arms*. Although my gossamer cartridge equally answers for breech-loader sporting guns, yet the breech-loading are few in proportion to the muzzle-loaders. And the *million* of guerrillas that I propose to follow my instructions, have only muzzle-loading sporting guns. Perhaps you will be so kind as to set this matter right in your next Magazine, as there are too many cavillers in official positions who would be ready to take advantage of the slightest slip.—J. NORRIS."

Trials which have been made at Chatham recently appear to show that, in addition to their many other advantages, Major Rhodes' tents are capable of being pitched and struck in considerably less than half the time necessary for performing the same operations with an ordinary tent.

Crystal Palace season tickets, available until May next, are now issued at the uniform rate of half-a-guinea; and as, coupled with this arrangement, it is the intention of the directors to enclose and improve the concert-room, so as to render it more generally available for winter concerts, lectures, &c., during the autumn and winter, there is little doubt that a more than ordinary attendance will be maintained during the coming six months. It is during this period of the year that the Crystal Palace becomes most available. Designed by Sir Joseph Paxton especially as a winter garden, it enables the visitors to enjoy exercise and recreation in defiance of the changes of climate so frequent in England; and, as the approaches from the railway are all under cover, the palace can at all times be reached without inconvenience. It is with the view of enabling the public to appreciate more fully these peculiar advantages of the palace, that the half-guinea season-tickets have been issued, and it is gratifying to find that they have already been taken up to a considerable extent.

The National Defence Commission embarked on Monday at Portsmouth on board the *Sprightly*, and, with a Government pilot on board, proceeded to the Needles to inspect the western approaches to Spithead.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgement:—

STEAM ENGINES, &c., 121.
 BOILERS AND THEIR FURNACES, &c., 174, 188.
 RAILS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 127, 131, 166.
 SHIPS AND BOATS, including their fittings, 133, 137, 170, 190, 200.
 CULTIVATION OF THE SOIL, including agricultural and horticultural implements and machines, 138, 136, 173, 180, 183, 184, 195.
 FOOD AND BEVERAGES, including apparatus for preparing food for men and animals, 153, 151.
 FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 132, 141, 141, 146, 148, 152, 153, 160, 162, 175, 178, 182, 185, 191, 196.
 BUILDINGS AND BUILDING MATERIALS, including sewers, drain-pipes, brick and tile machines, &c., 128, 155, 161, 176, 208.
 LIGHTING, HEATING, AND VENTILATING, 126, 129, 140, 192, 194.
 FURNITURE AND APPARATUS, including household utensils, time-keepers, jewellery, musical instruments, &c., 124, 147, 164, 169, 171, 179, 187, 202.
 METALS, including apparatus for their manufacture, 132, 134, 139, 145, 163, 210, 211.
 CHEMISTRY AND PHOTOGRAPHY, 126, 149.
 ELECTRICAL APPARATUS, 181.
 WARFARE, 157, 207.
 LETTER PRESS PRINTING &c., 135.
 MISCELLANEOUS, 123, 125, 150, 156, 142, 143, 150, 151, 159, 165, 167, 172, 177, 186, 189, 193, 197, 198, 199, 200, 201, 203, 204, 205, 206, 212.

121. T. SAMPSON. "Improvements in apparatus for feeding steam boilers with water." Dated Jan. 13, 1859.

Here at a level above the water in the steam boiler is a receiver or vessel from which the boiler is from time to time supplied with water, such vessel being of a strength suitable for resisting a like pressure to that in the steam boiler. A steam pipe from the boiler rises to the upper part of such receiver or supply vessel; there is only a water pipe which is fixed to the lower part of the receiver or supply vessel, and descends to nearly the bottom of the steam pipe, and on the water pipe is a cock, and it is preferred that these two cocks should be connected together and simultaneously opened and closed. The supply vessel or receiver receives water from an open tank above, or it may be from an open vessel or well several feet below the boiler; in either case there is a supply pipe leading from the receiver or supply vessel to the tank or well, and on such pipe is a cock which is to be opened when the two cocks above mentioned are closed, and *vice versa*. All the three cocks are connected together by connecting rods and levers put in action by a float in the boiler, with a weight to reverse the cocks on the instant. There is an air cock at the upper part of the receiver or supply vessel to allow the air to flow out when the supply vessel is first filled out with water. *Patent completed.*

122. S. HOLT. "A new and improved manufacture of woven silk fabrics." Dated January 14, 1859.

This consists in treating spun silk thread by saturating it in a solution of gum and water or a solution having equivalent chemical properties, and then in drying the thread so treated and weaving it into the fabric required; and afterwards in subjecting the fabric to heat and pressure combined to produce the requisite appearance. *Patent completed.*

123. M. A. F. MEXXONS. "A new or improved time measurer." (A communication.) Dated Jan. 14, 1859.

This consists in applying to time measuring apparatus the gradual flow or infiltration through porous bodies of fluids in general, and especially of air and gases. *Patent abandoned.*

124. W. CRAFT AND T. WILSON. "Improvements in drawers and napkins so as to render the same waterproof." Dated Jan. 14, 1859.

The object here is the manufacturing of drawers and napkins of a waterproof material having elastic bands or fastenings at their upper and lower extremities obviating the necessity of strings and buttons. *Patent completed.*

125. W. DAVIS. "Improvements in sluice valves." Dated Jan. 14, 1859.

Here the case is cast with a recess on one side of the water way into which the valve passes, when it is opened. The valve is circular when it closes the water passage, and it may be made with one or two bearing surfaces. The valve turns on an axis, and it is moved by means of a screw in the following manner:—The valve has a projecting arm beyond the axis of its motion, and such axis of motion is on one side of the water way or passage. To the arm or projection of the valve is attached a rod with a screw formed thereon. The pin by which the rod is attached to the arm of the valve works in a slot formed through the arm. The screw works through a stuffing box, which is kept tight by a suitable gland through which the end of the screw rod passes, and it enters a hollow tubular screw key, which is closed at its outer end, and it is fixed to the gland of the stuffing box by a second gland or cover through which the hollow key passes, and by reason of its inner end being formed with a projecting flange it turns fluid tight in a recess formed in the outer gland, so that the key can be turned and yet remain fluid tight. The recess for the valve is closed by a hollow cover fixed to the case by screws and nuts, and the screw rod works within such hollow, and the stuffing block through which it passes is formed at one end of such hollow cover. *Patent completed.*

126. J. DAUGLISH. "Improvements in obtaining carbonic acid gas." Dated Jan. 14, 1859.

Here carbonate of lime or other alkaline earth is distilled in a closed retort; the carbonate is placed in the retort, which is then closed so as to leave no communication between the atmosphere and the interior of the retort. The retort is heated externally by a fire, and is connected by a pipe with an air pump or apparatus for maintaining a vacuum within the retort; by this apparatus before the distillation commences the air is removed from the retort, and a mixture of the gas with air is thus avoided. As the distillation progresses the air pump or apparatus removes the gas from the retort as quickly as it is evolved, and it may be caused to pass into a gasometer in which it is stored for use. *Patent completed.*

127. R. ROMAINE. "An improved arrangement of portable railway." Dated Jan. 14, 1859.

Here the patentee causes distinct series of rails and sleepers alternately to come into use and sustain the pressure of the carrying wheels on the same axle, and applying sets of rails to the periphery of each wheel, so as to insure the placing on the ground of a rail of one set for its wheel to bear upon, before the pressure of the adjacent wheels is taken from the railway. The invention is not fully described apart from the drawings. *Patent completed.*

128. J. ECCLES. "Improvements in the manufacture of articles from clay earthen for building purposes, as substitutes for such articles as are usually formed of stone and other materials." Dated Jan. 15, 1859.

Here the patentee takes the material as free from impurities as possible, and moulds it into the required shape, either by compressing the material through moulding orifices, or by placing it in mould boxes. At the time of moulding he makes hollows or perforations of such number and extent as the shape of the articles admit of, then removes the articles to be subjected to the drying action of currents of air both hot and cold, produced by mechanical means, as described in the specification of a previous patent. *Patent completed.*

129. W. H. E. MCKNIGHT. "An upright celled boiler, applicable to all heating purposes by hot-water or other fluid." Dated Jan. 15, 1859.

This invention consists in constructing a boiler with a series of upright cells so arranged as to obtain a maximum heating surface, and at the same time to allow an unimpeded circulation of the water as it becomes heated, from the ingress to the egress pipes, by which the currents are accelerated and the heating medium transmitted more rapidly through the pipes. *Patent completed.*

130. P. A. VIETRE. "Certain inks applicable for engraving and lithographic purposes." Dated Jan. 15, 1859.

This consists in combining in certain proportions the following substances:—Gutta-percha, or caoutchouc, stearine tallow or white wax, lithographic or lamp black, turpentine, bitumen, or bituminous lac and white varnish. *Patent completed.*

131. D. L. BANKS. "Improvements in the method of constructing a travelling suspension rail or roadway, to be used for the cultivation of land." Dated Jan. 15, 1859.

This invention is not described apart from the drawings. *Patent completed.*

132. R. MCHET. "Improvements in the manufacture of cast steel." Dated Jan. 15, 1859.

The patentee claims the addition of a triple com-

pound consisting of, or containing, iron, carbon, and manganese to cast-steel produced by melting granulated cast-iron, or granulated refined cast-iron, and pulverised iron ore or oxide of iron, so that the said triple compound may be melted and combined with the cast-steel in the melting pots or crucibles. *Patent completed.*

133. W. BERRY. "Improvements in the manufacture of capsules, and in the apparatus to be employed therein." Dated Jan. 15, 1859.

Here the capsules are formed of the usual metal, but much thicker than those ordinarily made. The patentee takes a mandril having on it an external screw of the same size as a screw formed on the neck of a bottle, and the capsule being placed in the screw mandril, the mandril and capsule are caused to rotate, and at the same time by the action of the screw, they are moved in a lateral direction. A small disc is then pressed against the capsule, which forces it into the indentations of the screw mandril, and at the same time embosses the raised portions of the screw, and a stiff screw capsule is formed. *Patent completed.*

134. R. MCHET. "An improvement or improvements in the manufacture of cast-steel." Dated Jan. 15, 1859.

The patentee claims the manufacturing of cast-steel from mixtures of the following materials melted and combined together in melting pots or crucibles, the said materials being used either with or without the addition of charcoal or other carbonaceous matter. 1. Cast-iron which has been wholly or partially decarbonised by air having been passed through it whilst in a melted state. 2. Deodorised iron ore. 3. A triple compound of iron, carbon, and manganese, such as the "Spiegel Eisen" produced in Rhenish Prussia. *Patent completed.*

135. W. MORGAN. "Improvements in printing and stencilling, and in the apparatus or machinery used therein, also for certain applications of such printing and stencilling." Dated Jan. 17, 1859.

Here the inventor connects with wheels, or wheeled or other vehicles, one or more cylinders or segments thereof, which are to revolve on points or axles. These cylinders are to be moved by adhesion bands, toothed wheels, or pinions. On the surface of these cylinders the inventor fastens types or letters, and figures or designs. The cylinders revolve by the action of the wheels or otherwise, when moving the vehicle on the ground or elsewhere. The cylinders having been inked by inking rollers suitably placed, are rolled on the surface to be printed. He also places the type, &c., on bands by rivets, screws, nuts, glue, &c. These bands are to pass under the cylinders, and round, over, and under the cylinders, the object being to extend the printing surface beyond that of the circumference of the wheels or cylinders, in order that great spaces should sometimes be between each impression. *Patent completed.*

136. T. EDWARDS. "Improvements applicable to letter-boxes and other like receptacles." Dated Jan. 17, 1859.

This consists in cutting off communication between the upper and lower portions of the box during the time the receiving port is open by means of a flap valve jointed horizontally across the back of the box, and which is operated by the flap which closes the receiving mouth. *Patent abandoned.*

137. J. MONTGOMERY. "Improvements in the construction of the hulls of steam and other vessels, and in the feed-water heaters, boilers, water-gauges, condensers, engines, and propelling machinery appertaining to the former, a portion of which improvements (with the exception of those on the hull), are applicable to analogous useful purposes." Dated Jan. 17, 1859.

This invention is not described apart from the drawings. *Patent completed.*

138. E. T. HUGHES. "Improvements in machinery or apparatus for sowing seed." (A communication.) Dated Jan. 17, 1859.

This consists of a hopper divided into compartments, a moveable axle-tree as a distributor, and a sower or spreader having a series of spoons or blades tapered at the bottom to act as cutters or ploughshares, the said apparatus being fixed on a carriage with wheels. *Patent abandoned.*

139. P. A. DE ST. S. SICARD. "An improved process and apparatus for converting cast-iron into steel." Dated Jan. 17, 1859.

The patentee claims, 1, the oxidation and purification of cast-iron by causing the melted cast-iron in conjunction with nitrate of potash, or soda, or other nitrates or oxydising re-agents, to be rapidly granulated or reduced to powder by a percussive oxydising granulator for striking or projecting it against a surface or grating. 2. The application of carbonate of ammonia in the carburising process, and for decarburising the melted metal. 3. The application of nitrate of potash, or soda, or other nitrate by means of

a perforated box or case plunged into the melted metal for decarburizing and purifying it. 4. The above processes in combination. 5. The granulator. *Patent completed.*

140. S. T. COOPER. "Improvements in the use and application of artificial light." Dated Jan. 17, 1859.

The essential condition of this invention is to place a burner supplying a small jet of gas in such a position under or near to other burners that, the jet from the former being ignited, its flame shall ignite the gas from the latter when turned on. The means proposed for effecting this object is to lay down two pipes for the conveyance of the gas to be used, one of a small diameter to supply the gas to the burner with the single jet, the other of a diameter sufficiently large to supply the gas to the burners which are to be used for illuminating purposes; or the small pipe may be a branch from the larger one. *Patent abandoned.*

141. W. E. NEWTON. "An improvement in sewing machines." (A communication.) Dated Jan. 17, 1859.

This invention is not described apart from the drawings. *Patent completed.*

142. E. BROOKS. "Improvements in locks." Dated Jan. 17, 1859.

According to this invention the locks are formed with a curtain, consisting of a plate which moves on a pin or otherwise in front of the keyhole, so as to close it, with the exception of the central opening, by the motion of the lock. The bolt shoots twice by one turn of the key, whereby great security is obtained. *Patent completed.*

143. R. G. SALTER. "Improvements in apparatus for collecting or picking up letters, papers, and other articles requiring to be stamped or printed." Dated Jan. 17, 1859.

Here the patentee places the letters edgewise upon an inclined feeding tray or trough, and between or upon endless belts, which conduct them against the side of a revolving cylinder, containing on the inside one or several apparatuses for exhausting air, and perforations at intervals in the side. The face of the cylinder carries stamps or dies, which are inked upon the revolution of the cylinder by contact with an inking roller. Over another part of the cylinder is a pressure roller. The operation is as follows:—As soon as an aperture or series of holes comes opposite the feeding trough, one letter is drawn by the exhaustion of the air inside the cylinder, and held against the side of the cylinder and over the stamp or die which has been inked; the cylinder continues to revolve with the letter adhering thereto, and carries it under the pressure roller. *Patent completed.*

144. G. and J. COLLIER. "Improvements in means or apparatus for washing and drying wool and other fibres, part of which improvements are also applicable for other purposes, where steam, hot water, or other fluids are required to be conveyed under pressure through moveable connections." Dated Jan. 17, 1859.

Here the fibre, &c., is fed on to an endless apron, by which it is conveyed to another apron, and it by these aprons conducted forward and into the water or other wash liquid, and whilst the fibre is so conducted the wash liquid has motion given to it by revolving heaters to cause it to pass fully through the fibre. The fibre is afterwards conveyed to expressing rollers and dried by steam. *Patent completed.*

145. R. MURPHY. "Improvements in the manufacture of cast-steel." Dated Jan. 17, 1859.

This consists in manufacturing cast-steel by melting and combining scrap-steel, bar-steel, or blister-steel, or any mixtures of these, with wholly deoxidised iron ore and a triple compound of iron carbon and manganese. Also in mixing with the above charcoal or other carbonaceous matter. *Patent completed.*

146. J. LUIS. "A new machine for putting on, equalising, and drying the colours on paper for hangings, bookbinding, boarding and fancy paper of every description." (A communication.) Dated Jan. 18, 1859.

The principle on which this invention rests is the triple rotation of brushes imitating the work performed by the workman. The triple rotation of brushes is obtained by a disc having a continued circular movement communicated to it by bevil wheels or pulleys, placed on a longitudinal shaft, which receives its movement directly from the driving shaft. *Patent abandoned.*

147. W. NEWMAN. "New or improved furniture for window and other blinds." Dated Jan. 18, 1859.

This invention is not described apart from the drawings. *Patent completed.*

148. J. FOSTER. "Certain improvements in machinery or apparatus called 'spinning frames' and 'roving frames' employed for spinning and roving

flax, tow, hemp, jute, and other fibrous substances." Dated Jan. 18, 1859.

This invention is not intelligibly described apart from the drawings. *Patent completed.*

149. G. HAMILTON. "Improvements in treating resin and resinous substances to obtain products therefrom, and in treating the products obtained from resin and resinous substances." Dated Jan. 18, 1859.

The object here is to obtain from common resin direct by one distillation a variety of clear and pale oils. *Patent completed.*

150. H. GALLOW, J. H. BEAN, and S. LUMP. "Improvements in machinery for slotting, morticing, tenoning, and cutting wood, iron, and other substances." Dated Jan. 18, 1859.

This consists in the application of a crank or eccentric to such machines, in order to actuate the cutting tool, such crank or eccentric acting with a slide arranged to move in a slot formed in the spindle which carries the cutting tool. *Patent completed.*

151. C. D. ARCHIBALD. "Generating force." (A communication.) Dated January 18, 1859.

The nature of this invention consists in so constructing a piston or its equivalent that when acting under the pressure of fluid bodies the resistance it meets or generates shall be made to assist the process of displacing, condensing, or exhausting without waste of the elements employed. The invention is not described apart from the drawings. *Patent completed.*

152. R. A. BROOMAN. "An improved silk thread, and a new fabric made entirely or partially from the same." (A communication.) Dated Jan. 18, 1859.

The patentee claims the manufacture of an improved silk thread by combining silk waste ("soie fantaisie") with raw or other silk by any suitable means. Also, the manufacture of a new fabric by forming a fabric having the said improved silk thread either in whole or in part as a warp, or as a weft, or as both, by any suitable means. *Patent completed.*

153. "R. GARRETT, jun., and J. KERBRIDGE. "An improved arrangement of combined threshing and dressing machines." Dated Jan. 18, 1859.

This consists chiefly in providing a single fan which draws into its case a large volume of air, and by reason of its connection with a system of air trunks and passages cause the discharge of the air at any given number of vents in broad streams suitably directed for impinging upon the falling grain and chaff. *Patent completed.*

154. J. FAWCETT. "An improved preparation of food for cattle and horses." Dated Jan. 18, 1859.

The patentee claims particularly "the use of the locust pod and bean, in combination with other suitable farinaceous substances, and the preparation of the combined ingredients in the form of cake." *Patent abandoned.*

155. R. BRADLEY and W. CRAVEN. "Improvements in machinery or apparatus for manufacturing bricks, tiles, and other similar articles." Dated Jan. 18, 1859.

This relates to apparatus for manufacturing bricks, tiles, &c., from pulverized clay by compression, the main object being to obviate the difficulties usually attendant upon the pressure of air in the material under pressure. The details are voluminous. *Patent completed.*

156. W. TROTTER. "Improvements in reaping machines." Dated January 18, 1859.

This consists in arranging the parts of reaping machines so that the parts may readily accommodate themselves to the inequalities of the ground. *Patent completed.*

157. J. H. JOHNSON. "Improvements in air pistols and guns." (A communication.) Dated Jan. 18, 1859.

This relates to children's air guns and pistols. The breech-piece is moveable, and the butt is made hollow for containing a reserve of charges. *Patent abandoned.*

158. J. THORNTON. "Improvements in carding engines." Dated Jan. 19, 1859.

This relates to applying an endway traverse motion in addition to the ordinary rotary motion to the first toothed cylinder or roller receiving fibre from the feed means, or that which delivers to the main cylinder of a carding engine in order thereby more intimately to mix or even distribute the fibres to be carded. *Patent abandoned.*

159. W. A. F. POWELL. "Improvements in stopping or closing jars and bottles." Dated Jan. 19, 1859.

Here the stopper is formed of glass or stoneware, with a shoulder on its under side, which fits on to a plain or grooved seat within or upon the neck of the jar or bottle, and an interposed washer of india-rubber. *Patent completed.*

160. P. A. SPARKS. "Improvements in the manu-

ture of paper, suitable for bank-notes, cheques, bills, and similar articles." Dated Jan. 19, 1859.

This consists in applying to the paper in the course of manufacture a material capable of producing therein an opaque body either white or in one or more colours, and of any required pattern or design, which opaque body will not interfere with the clearness of the printing on the surface of the paper, but will become visible so as to appear mixed up with the subject of such printing when the note, cheque, bill, &c., is held up to the light. The opaque body consists of a body not soluble in water, such as Prussian blue, red lead, white lead, &c. *Patent completed.*

161. T. CLARKE. "Improvements in the manufacture of core barrels for pipes or columns used either for railway pipes or columns, or for water pipes or for sewerage pipes." Dated Jan. 19, 1859.

Here the patentee constructs a core barrel with two rows of hinges, and without a slide or key, but with three stay bars, which stay bars, when loosened, as can be easily done, allow the core bar to leave the casting without impediment. *Patent completed.*

162. E. T. HUGHES. "Improvements in machinery or apparatus for measuring and sorting silk and other textile materials." (A communication.) Dated Jan. 19, 1859.

Here the silk, &c., is wound on bobbins or spools to a certain length, and measured with exactness by a meter or measuring machine, which stops the movement of the bobbins or spools at the time required. To sort or assay the silk, &c., the external diameter of each bobbin or spool is measured or gauged and weighted. *Patent completed.*

163. J. WHITEHEAD. "Improvements in the means or machinery for the manufacture of 'purl' wire." Dated Jan. 19, 1859.

This consists in causing the wire to wind around a taper pin at the end of a spindle having a rotary motion. A strap presses on the outside of the coil, and has a rotary motion in the same direction as the taper pin. *Patent completed.*

164. E. STEVENS. "An improved cooking utensil." Dated Jan. 19, 1859.

This consists in combining in one a meat stand, a vegetable dish, a pudding and pie dish, and a stew pan. *Patent completed.*

165. T. A. EVANS and W. J. H. RODD. "A new method of advertising." Dated Jan. 19, 1859.

This consists in making use of the bowls and stems of tobacco pipes as a medium for advertising. *Patent abandoned.*

166. W. POUPARD. "An improved wheel-skid or shoe." Dated Jan. 19, 1859.

This consists in constructing a skid or shoe for the skidding of wheels in descending inclines with a tail piece projecting from the back part and top of the skid chamber. This tail piece may be carried entirely through to the front of the shoe, and the patentee prefers to form it of wrought iron or steel, while the body of the shoe may be made of cast or wrought iron. *Patent completed.*

167. J. H. JOHNSON. "Certain improvements in the manufacture or production of lasts, boot-trees, and clogs, and in the machinery and apparatus employed in the production of such articles." (A communication.) Dated Jan. 19, 1859.

The specification of this invention is arranged under eleven heads, and the invention is not fully described apart from the drawings. *Patent completed.*

168. J. H. JOHNSON. "Improvements in apparatus for making cigarettes." (A communication.) Dated Jan. 19, 1859.

This consists, 1, in making cigarettes less tapered than heretofore; 2, in the use of paper tubes cut down to a certain distance; 3, in making the lower portion of the head of the rammer conical; 4, in addition to the upper portion of the rammer head of a cylindrical part slightly hollowed for closing the thick end of the cigarette; 5, in the use of a paper mouthpiece fitted internally with a perforated diaphragm; 6, in marking divisions on the rammer; 7, in making the mould of metal, and the funnel of caoutchouc. *Patent completed.*

169. W. CLARK. "Certain improvements in boots and shoes, and in the machinery, apparatus, and means employed in such manufacture." (A communication.) Dated Jan. 19, 1859.

This embraces various features which to be rendered intelligible must be given in detail, and that our space will not admit of. *Patent abandoned.*

170. J. C. REID and W. MILNER. "Certain improvements in the construction of ships and vessels." Dated Jan. 20, 1859.

This consists in so constructing the bulkheads that the separate compartments into which a ship may be divided may be secured against the extension of fire. The bulkheads are to be formed of two walls or plates of iron, and placed across the ship in parallel posi-

tions, and so as to form a hollow wall or chamber. This chamber is to be filled with a fire-resisting composition. *Patent completed.*

171. H. HILLIARD and T. CHAPMAN. "Improvements in table-knives, and in table-knife sharpeners." Dated Jan. 20, 1859.

In making the "lock'd-fast" handle lateral holding projections are formed upon the tang at a short distance from the blade of the knife. The lateral holding projection may be formed with an acute longitudinal edge by which the holding recess may be formed in the handle; or the projections may be shaped like segments of screws, which may top themselves into the sides of the handle bore, and by their screw action draw the tang well into the bore. In making an "accumulator" under one modification, the wheels or steel discs may be arranged as in common sharpeners of the same class, it being preferred to use two wheels on one side with one projecting slightly between them on the other, but the mounting is formed in such a way as to guide the knife obliquely or diagonally in being drawn across the wheels. *Patent completed.*

172. A. LINDO. "Improvements in manufacturing soap." Dated Jan. 20, 1859.

This consists, 1, in a new process for the manufacture of soluble and insoluble soap; 2, in an improvement in the preparation of lyes for the manufacture of soap; 3, in the addition of certain substances or chemical matters which being added to soap made by ordinary means renders it more durable. The details of the invention are too voluminous to be quoted here. *Patent completed.*

173. W. WOOLFE. "Improvements in implements for ploughing, tilling, and paring land." Dated Jan. 20, 1859.

This consists in forming that part of the beam to which the shares or parers or other tools for acting on the soil are affixed in the shape of a frame, so that two or more sets of shares, parers, or tools, may be fitted to the same beam. The inventor hinges this frame at front, and on an independent frame he mounts an axis for carrying a front or guide wheel. At the back of the frame carrying the shares, &c., he places two large wheels, and causes them to travel within the path of the shares, &c. The beam frame, front wheel frame, and handles are so combined and united that upon depressing the handles, the shares, &c., are released from the soil, and the implement may then be moved or turned upon its wheels. Another part of the invention consists in forming a skeleton or open work mould-board for parers when used for paring stubble, and instead of fitting the shank of paring knives in parers closely in the eye or loop, he makes the loop sufficiently large to enable wedges or screws to be used to effect the fastening. By employing wedges and screws the knives may be readily removed; they also admit of adjustment according to their wear. *Patent abandoned.*

174. E. T. HUGHES. "Improvements for preventing incrustation in steam-boilers or other vessels." (A communication.) Dated Jan. 20, 1859.

Here the inventor employs shells, or receptacles, made of plates of metal, placed a short distance from the bottom and sides of the boiler, and also near the flues or tubes, the shells having openings so placed as to cause the fluid to circulate at a greater velocity, or be more agitated at those parts, when the boiler is in contact with the heat, which prevents the sediment from settling upon the heated parts. *Patent abandoned.*

175. T. GREENWOOD and J. BATLEY. "An improvement in the process of gassing textile fabrics." (A communication.) Dated Jan. 20, 1859.

This consists in directing the flame towards the fabric as it is travelling forward over rollers, which holds it at tension on a vertical plane on approaching the flame, by which means the fabric is brought into contact with the oxygenated portion only of the flame. *Patent completed.*

176. S. PHILLIPS. "Improvements in sliding sashes, shutters, or doors." Dated Jan. 20, 1859.

This invention is not described apart from the drawings. It consists in dispensing with pulleys, sash lines, and weights. *Patent completed.*

177. W. E. NEWTON. "Improved apparatus for measuring water and other liquids." (A communication.) Dated Jan. 20, 1859.

Here the pipe through which the liquid flows is provided with a socket for the reception of an upright tube of glass, open at bottom; in this vertical glass tube, which is furnished with a graduated scale, is inserted a rod of alabaster, or other substance which is but slowly dissolved by water. This soluble rod rests at its lower extremity in the water-pipe. As, therefore, the lower end of the rod of soluble material is dissolved away by the water, it will gradually descend,

and indicate upon the graduated scale the quantity of water which has acted upon it. *Patent completed.*

178. T. GREENWOOD, J. BATLEY, and J. DOCKRAY. "Improved machinery for converting hemp and flax fibres into yarn, twine, ropes, and cordage." Dated Jan. 20, 1859.

This relates, 1, to machinery for drawing hemp and flax fibre, and consists in conveying the fibres from the retaining rollers to the drawing-off rollers by an endless band of gills or comb teeth constructed according to a method patented 9th April, 1858. It relates, 2, to the wet spinning frame used for spinning flax, and consists in mounting the retaining rollers and the back drawing-off rollers on separate beams, and rendering the beam which carries the retaining rollers adjustable by means of a rack and pinion and worm and worm wheel. It relates, 3, to machinery for dressing yarn and twisted fibres, and consists in combining with a series of friction or polishing cylinders geared carrying rollers for passing the fibres forward from one polishing surface to the next. It relates, 4, to a mode of delivery to the apparatus for laying twine cordage, &c., a regulated quantity of yarn or strands, into which, while being delivered from their bobbins, a uniform twist is thrown. *Patent completed.*

179. J. BENT. "Certain improvements in clasps or fastenings, applicable for belts, garters, and other purposes." Dated Jan. 20, 1859.

This invention is not described apart from the drawings. *Patent completed.*

180. J. SHANKS. "Improvements in mowing machines." Dated Jan. 20, 1859.

This relates to "lawn-mowing machines." The two driving rollers are loose on the shaft, and on the centre or nave of each roller is cast or fixed a clutch, or engager, which works into a clutch on the shaft on which the two rollers revolve. These rollers are loose, and are prevented from turning round by a sunk key in each. Between each clutch and in the centre is placed a spiral spring, composed of iron or steel wire, which keeps the clutches always in gear, and at the same time allows the machine to turn easily. The gear for shifting the machine to the required cut consists of a bracket fitted to each side of the machine a little in front of the cutter. A socket is cast on the bracket in each case, into which a spindle is fitted having a forked end to contain a small pulley. It is on these pulleys that the fore part of the machine rests. A toothed rack is fixed or cast on the bracket, into which a pinion works. There is a pinion on each end of a shaft working across the machine, on one end of which is placed a handle, so that by turning the shaft by the handle the bracket is made to move upwards or downwards to get the required length of cut. The apparatus for emptying the grass box consists of a rod or lever, which is made to turn backwards or forwards on a pivot or other joint fixed on the back rail or other part of the machine. One end of the rod is fixed by two or more joints to a false end in the grass box; the other end is lengthened till it reaches the stilt or shafts, and this end is made into a handle, and by a simple throw of the handle from one side to the other, the grass is thrown out of the box by the travelling end. *Patent abandoned.*

181. J. L. CLARK and J. MUIRHEAD. "Improvements in electric telegraphs, and in the apparatus used for working the same." Dated Jan. 20, 1859.

This consists, 1, in constructing the horizontal portion of the support or bracket used for supporting the line wire insulators hollow, using malleable cast-iron, and subsequently annealing the same. 2. In serving the gutta-percha or india-rubber coating of telegraph wires with a coating of fine fibre of grass spun into a yarn or cord, and saturated with pitch, shellac, &c. The invention also comprises a method of constructing lightning conductors for telegraph wires, "detectors" for electrical purposes, and improvements in the magnets for magnetising the needles of telegraph instruments. The details of these last-mentioned features are voluminous. *Patent completed.*

182. H. SAGAR and A. SCHULTZ. "Improvements in producing pink shades on cotton fabrics or yarns." Dated Jan. 20, 1859.

The patentees first boil the cotton pieces or yarns (previously bleached) in a solution made by dissolving murexide in a solution of nitrate of lead, to which they add a solution of bichloride of mercury. The pieces when treated in this manner became a brownish red colour, and the object of the invention is to change this tint, which has heretofore been produced when dyeing with murexide into a pink colour. They do by the use of alkalies, alkaline salts, acids and salts, and acetate of soda mixed with wheaten starch, flour, farina, gums, &c. *Patent completed.*

183. T. RICHARDSON. "Improvements in the manufacture of manure." Dated Jan. 21, 1859.

This consists in absorbing the acid by some organic material, such as sawdust or others, then mixing the phosphatic substance with this acid mixture, and allowing the whole to remain until the ordinary decomposition is completed. *Patent completed.*

184. S. OSLER and J. B. BALCOMBE. "Improvements in apparatus for treating fish, so as to adapt it for manure, and in using the same alone or in combination with super-phosphate of lime or other phosphates." Dated Jan. 21, 1859.

This consists, 1, in treating fish by applying thereto the heat of steam or heated vapour in the manner and by means of certain apparatus. 2. In the admixture of about from 30 to 50 per cent. of the aforesaid prepared fish with either manufactured super-phosphate of lime, or with ground or calcined coprolites. *Patent abandoned.*

185. L. LE PRINCE. "The improvement of ladies' boots and shoes, called the caméleon boot and the caméleon shoe." Dated Jan. 21, 1859.

The patentee constructs ladies' boots and shoes with ornamental perforations or pierced work in the upper leather or outer material, and makes a cavity between this portion of the upper leather or material and the lining, and inserts into this cavity a moveable piece of cord, or leather, or cloth, or other material of any required colour, or covered with silk or cloth. *Patent completed.*

186. G. B. HARKES. "An improved machine for washing, wringing, and mangling." Dated Jan. 21, 1859.

This machine consists of a trough which contains the water, and on which trough are placed two horizontal bars of wood, each bar having a horizontal slot for admitting the articles to be washed. Near the slotted bars two rollers are placed which turn upon their axes, the distance of the rollers from each other being adjustable. An endless band of canvas, &c., passes over the lower roller through the slotted bars, and over a small roller placed within the trough or reservoir. The slotted bars receive a reciprocating vertical motion from a fly-wheel and crank or otherwise. *Patent abandoned.*

187. G. ELLIS. "The improvement of muffs, to be called the patent reticule muff." Dated Jan. 21, 1859.

The "reticule muff" is a muff made with one or more bags inside, the opening of the bag or bags being at top or upper side of the muff, and the same closing up with snaps, &c. *Patent abandoned.*

188. J. HICK and W. HARGREAVES. "Improvements in the construction of steam boilers." Dated Jan. 21, 1859.

This consists in the use of T iron for forming the joints between the plates or hoops of which the internal flues of boilers or the shells of boilers are constructed. *Patent abandoned.*

189. R. HOWELL and R. J. WILLDER. "An improvement or improvements in taps or stop cocks." Dated Jan. 21, 1859.

This consists in the use of a packing or lining inserted and fixed in slots or depressions in the barrel of the tap or stop cock, against which said packing the plug of the stop cock works, and the said stop cock is thereby made water, gas, or steam tight. *Patent completed.*

190. C. O'HARA. "Improvements in propellers, for propelling steam-boats, ships, and vessels." Dated Jan. 21, 1859.

This invention is not described apart from the drawings. *Patent completed.*

191. W. WELLS. "Improvements in machinery or apparatus employed in spinning and twisting cotton, and other fibrous substances." Dated Jan. 21, 1859.

This relates to self-acting mules and jennies, and consists in the use of a screw or screw-shaft for putting up and drawing out the carriage instead of bands and pulleys. *Patent abandoned.*

192. A. DAVENPORT. "An improved regulating burner for gas." (A communication.) Dated Jan. 21, 1859.

This invention is not described apart from the drawings. *Patent abandoned.*

193. J. CHILDS. "An improvement in applying heat in the manufacture of artificial gums and teeth, and other articles composed of india-rubber, or gutta-percha, combined with sulphur." Dated Jan. 21, 1859.

This consists in applying superheated steam for the purpose. *Patent completed.*

194. J. H. HUMPHREY. "Improvements in warming apparatus for the feet." Dated Jan. 21, 1859.

This consists of a metal case or shallow chamber to be attached beneath the sole of the boot or shoe, and having one of its sides capable of being opened and closed. This metal chamber has fitted within it a sole piece of brick, fire-clay, &c., which is inserted in its place for use in a heated state. *Patent completed.*

195. A. J. A. GANTIER, J. G. DUMAY, and J. T.

PERRIN. "An improved manure." Dated Jan. 21, 1859.

This consists in mixing guano with peat. *Patent abandoned.*

196. W. H. MORRISON and H. KINDSEY. "Improvements in means or apparatus employed in the manufacture of bonnet fronts, ruffles, ribbon trimmings, and other guffered or plated articles." Dated Jan. 21, 1859.

This consists in means for pressing the edges of one or more rows of plated or guffered lace, &c., so as to form a flat edge on which a barrel may be applied. *Patent abandoned.*

197. J. NEWMAN. "Improvements in the manufacture of chains." Dated Jan. 21, 1859.

The patentee claims giving increased strength to draw, bench, suspension bridge, pit, and other such chains, by forming the axes of the links with recesses and bosses or curved projections. *Patent completed.*

198. B. LAUTH. "An improved mode of, and improved machinery for, rolling plates, bars, rods, and shafts." Dated Jan. 21, 1859.

Here the patentee uses pressing rollers, and causes the articles to be drawn to and fro between them by clamps or other attachments, to which a travelling motion is imparted. *Patent completed.*

199. J. EDWARDS. "Improvements in the manufacture of buckles." Dated Jan. 21, 1859.

This consists in making a link to square or whole frame buckles, so that the strap can be attached to the buckle without having a hole cut in it. *Patent abandoned.*

200. L. A. DROUIN. "Improvements in covering joinery work with metals or metallic alloys, and apparatus for the purpose." Dated Jan. 22, 1859.

The inventor makes use of a stretching or drawing bench or of a screw-press, each furnished with suitable dies, matrices, or blocks for the purpose named in the title. *Patent abandoned.*

201. D. MOSLEY. "Improvements in the manufacture of india-rubber thread." Dated Jan. 22, 1859.

This consists in forming solid cylindrical blocks of india-rubber, and then cutting these blocks into sheets; these sheets when lapped on to a roller with a layer of cement are then cut into thread by the ordinary cutting apparatus. *Patent completed.*

202. B. TEMPLAR. "Improvements in umbrellas and parasols." Dated Jan. 22, 1859.

This consists in placing a collar of metal on the rib, and fixing it without perforating the rib, and in forming a bearing on the under part of the collar to which the outer end of the stretcher is fastened by a pin, stud, screw, or otherwise. To connect the rib to the fixed ferrule at the crown of the umbrella or parasol, the patentee forms on or connects to the inner end of the rib a hook which he hooks over a ring, and confines that ring in the ferrule. In like manner to connect the stretcher to the sliding ferrule, he forms a hook in the inner end, and passes that over a ring fixed in the ferrule. *Patent completed.*

203. E. DOWSETT and J. B. BLYTHE. "Improvements in the distillation of oil from coal-tar, and in apparatus for preserving timber therewith." Dated Jan. 22, 1859.

The patentees claim, 1, the distillation of gas tar by a continuous process from the ordinary distilling vessel or vessels into other retorts, ovens, or stills. 2. The use and application of machinery for preserving railway sleepers and other timber with sulphate of copper and other preservatives. *Patent completed.*

204. M. HENRY. "Improvements in machinery or apparatus for manufacturing corks and bungs." (A communication.) Dated Jan. 22, 1859.

This specification describes an elaborate arrangement of details which can be thoroughly comprehended only by aid of reference to the drawings. *Patent abandoned.*

205. W. E. NEWTON. "Improved machinery for cutting files." (A communication.) Dated Jan. 22, 1859.

This consists, 1, in the use of a circular chisel, which is rolled over the blank; the chisel being so adjusted to the surface of the blank that it shall sink a given distance into it. 2. In holding that face of the blank which is being cut up against a face plate or rest by pressure against its opposite side. 3. In clamping the blank rigidly while a cut is being made and releasing it preparatory to its being fed. 4. In a device for holding the blank while a cut is being made. *Patent completed.*

206. T. W. RAMMELL. "Improvements in atmospheric propulsion, and the structures, tubes, machinery, and apparatus applicable thereto." Dated Jan. 22, 1859.

This invention is not described apart from the drawings. *Patent completed.*

207. C. SHARPS. "Improvements in breech-loading repeating fire-arms." Dated Jan. 22, 1859.

This relates to breech-loading repeating fire-arms in which a cartridge is used consisting of a case containing the powder with a bullet attached to one end of the case, and an enlargement or projection at the opposite end for containing the detonating material. It consists, 1, in discharging a number of the above described cartridges by a projection formed on the striking portion of the hammer, and caused to rotate by the movement of the hammer, the cartridges being so arranged in respect to the projection that it will strike the edge only of each cartridge in succession. 2. In the use of a sliding barrel-block with two or more bores, in combination with spring catches attached to the stock, by which the spent cartridges may be withdrawn simultaneously from their respective bores, on sliding the barrel from the fixed breech-piece. 3. In the use of a dog or catch, hung loosely to the hammer, and adapted so as to fit into a notch or recess in the stationary breech, so as to form a check for the hammer, and prevent premature discharge of the cartridges by maintaining it in contact with their detonating ends. 4. In introducing a hard steel centre-piece into the end of the barrel-block at such a point that it will form a species of anvil or base to receive the blow of the projection on the hammer, as the latter strikes each cartridge in succession. *Patent completed.*

208. R. BARTER. "Improvements in heating and ventilating buildings, and in apparatus connected therewith." Dated Jan. 22, 1859.

Here the inventor admits the air to the heating-furnace by a number of small apertures made underneath the fire-bars on each side of the ash-pit, the air being brought by flues or passages from near the ceilings of the hot rooms, and its place therein supplied by fresh air admitted near the floors. There are other features included. *Patent completed.*

209. W. C. HOMERSHAM. "Improvements in floating girdlons or stages for repairing ships or other vessels." Dated Jan. 24, 1859.

Here the patentee combines two series of hollow air-tight caissons placed transversely to each other, so as to form or constitute a rigid structure on which the platform for carrying the ship is fixed. *Patent completed.*

210. R. MUSHET. "Improvements in the manufacture of cast-steel and iron." Dated Jan. 24, 1859.

This consists in adding to cast-iron during the time that it is being decarbonised by the action of air forced or passed through it whilst in a molten state successive quantities of a triple compound consisting of iron, carbon, and manganese. *Patent completed.*

211. R. MUSHET. "An improvement in the manufacture of cast steel." Dated Jan. 24, 1859.

This consists in adding together, melting, and combining in melting-pots or crucibles the following substances:—1. Crude steel, which the patentee terms "iron-ore steel," obtained from iron ores or oxides of iron, first deoxygenised or deprived of their oxygen by cementation with carbonaceous matter, and then converted into a steel by a further cementation in contact with carbonaceous matter. 2. A triple compound consisting of iron, carbon, and manganese, such as the "Spiegel Eisen" of Rhenish Prussia. *Patent completed.*

212. R. A. BROOMAN. "Improvements in pumps." (A communication.) Dated Jan. 24, 1859.

This consists in constructing and arranging the parts of pumps as follows:—The barrel or cylinder of the pump is placed with its axis horizontal, and is furnished with four valves, two of which are in the upper side and near the ends, and two in the lower side near the ends. The two lower valves open into two suction pipes, which meet and lead by a single pipe into any suitable reservoir. The two upper valves open into a closed chamber which acts as an air chamber, and into which the delivery pipe dips. The piston which moves to and fro in the barrel or cylinder is formed of two discs, say of iron, between which are placed two larger discs of leather, or other like material, the edges of which turn over the edges of the iron discs and lie against the cylinder. The inner end of the piston rod passes through all the discs and has screwed upon the extremity of it a nut which keeps the whole together. The piston-rod is furnished at its outer end with a cross-head, the ends of which carry other rods passing back along the outside of the cylinder through guides on its sides. Above or below these rods are other rods oscillating on centres, and carrying handles like those of ordinary pumps. From the middle of these rods depend or stand up (as the case may be) grooved side pieces, in the grooves of which rollers attached to the side rods of the piston are confined, so that as the handles are worked up and down the piston rod and piston may thereby be caused to reciprocate. By mounting the

machine with a reservoir on wheels it may be made fit for use as a fire engine, and by connecting it with other suitable appliances it may be rendered applicable as a ship pump, or as any other ordinary kind of pump. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated July 30, 1859.

1768. A. B. Seithen. Improvements in cases or boxes, and in casings, hampers, baskets, and wrappers for holding bottles, jars, and other articles.

Dated Aug. 1, 1859.

1778. E. Merrell. Improvements in apparatus for washing and cleansing.

Dated Aug. 4, 1859.

1800. E. J. Corder. Improvements in the application of kites to the saving of life and property from shipwreck, and to other purposes.

Dated Aug. 5, 1859.

1808. R. T. Pattison. Improvements in dyeing certain woven fabrics.

Dated Aug. 8, 1859.

1822. J. Cunningham. Improvements in and connected with Jacquard apparatus for weaving.

1824. R. A. Brooman. Improved means of preventing incrustations in steam-boilers. A communication.

1826. L. B. Ollivier. Improvements in closing or stoppering bottles, jars, and other receptacles.

1827. B. Baugh. Certain improvements in the mode and apparatus for partially forming, and finishing the edges of certain description of vessels formed or raised from sheet iron or other metal.

1828. J. H. Johnson. An improved signal light, and in the apparatus employed in the production thereof. A communication.

1830. G. T. Bousfield. Improvements in revivifying the scarlet colour of woollen cloth, lace, and embroidery in use for military and other garments and furniture. A communication.

1832. J. B. Babcock. Improvements in umbrellas and parasols. A communication.

Dated Aug. 9, 1859.

1834. N. Kenward. Improvements in constructing tubular steam boilers.

1836. J. Cannon. Improvements in washing machines. A communication.

1838. C. L. J. Dierickx. A new system of scales, to be used principally in the fabrication of coins.

1844. W. Williamson. An improved machine or tool for drilling holes.

1846. J. H. Johnson. Improvements in destroying noxious exhalations. A communication.

Dated Aug. 10, 1859.

1850. T. A. Temperton. Improvements in pipes for smoking tobacco.

1852. G. Capper. Improvements in the permanent way of railways.

1854. J. J. Speed, jun. Improvements in the manufacture of pipes, tubes, and hollow cylinders.

Dated Aug. 11, 1859.

1855. R. and G. Heaton. Improvements in coin-machinery.

1857. J. T. Pitman. A composition applicable to the lubrication of machinery and to various other uses. A communication.

1858. W. Bouch. Improvements in breaks, in buffers, and in couplings to be used on railways.

1859. D. Hulett and G. Prudden. Improvements in apparatus for the manufacture and distribution of gas, and in apparatus applicable for internal or external illumination.

1860. W. De la Rue and Dr. H. Müller. Improvements in treating Japan and other vegetable wax.

Dated Aug. 12, 1859.

1862. W. Clark. Certain improvements in oscillating engines. A communication.

1863. A. Evaux. Artificial marbles.

1864. W. H. Tooth. Improvements in the mode of cleaning or laying the dust of pavements, roads, or other surfaces.

1865. J. Philp. An improved hobby-horse or child's exerciser.

Dated Aug. 13, 1859.

1867. D. Campbell. Improvements in the preparation of oils for medicinal and other purposes.

1868. J. Brown. Improving false shirt fronts.

1870. W. Green and W. and F. Fawcett. Improvements in the manufacture of rugs.

1871. B. Clegg and R. Fell. Apparatus for obtaining aerated fresh water from salt water.

1872. J. and W. Stuart. Improvements in nets for fishing, and for other purposes.

1873. K. Bühring. An improvement in obtaining spring power, and in its application to various purposes.

1874. R. I. Watts, J. Offord, and J. R. Thomas. A method of condensing and consuming smoke and other products of coals, ores, and similar substances, and reducing them to useful materials.

1875. H. T. Lambert. Improved apparatus to be adapted to ships' tackle or boats, for the purpose of facilitating the disengaging of ships' boats when lowered into the water. A communication.

1876. E. Sloman. An improved feed water and heating apparatus. A communication.

1877. J. R. Rostron. Improvements in locomotive furnaces.

1878. C. MATHER. Improvements in machinery for stretching, drying, and finishing fabrics.

Dated Aug. 15, 1859.

1879. S. Harrison. Broiling of chops or any other kind of meat.

1880. J. Jeyes. An improvement in the manufacture of boots and shoes.

1881. C. Kisky and W. Jones. Improvements in the construction of sideboards.

1882. C. Glassbrow. Improvements in pianos.

1883. J. Chanter and D. Annan. Improvements in apparatus for supplying air to furnaces.

1884. E. Stone. Improvements in machinery for cutting veneers. A communication.

1885. J. Poupard. A certain elastic combination to be used for blackleading stoves and other ironwork.

Dated Aug. 16, 1859.

1887. H. Batchelor. Improvements in steam and other motive power engines.

1889. W. Gossage. Improvements in the treatment of certain offensive liquids and of noxious gases liberated from such liquids.

1890. J. C. Haldan. Improvements in wads for projectiles, and in projectiles to be used therewith.

1891. J. C. Haddan. Improvements in machinery or apparatus for rifling cannon.

Dated Aug. 17, 1859.

1893. H. Medlock. Improvements in Portland and Roman cement, lime, and other similar kilns or furnaces.

1895. R. A. Brooman. Improvements in locks and keys. A communication.

1897. A. Yoekney. Improvements in refining and compounding oils or fatty matters with other substances for lubricating and other purposes.

Dated Aug. 18, 1859.

1899. J. Drabble. An improvement in sewing machines.

1901. H. J. Hyams. Improvements in the construction of wet gas-motors.

1903. W. Wilson. Improvements in the manufacture or production of bricks, tiles, and other articles of earthenware, and in the machinery or apparatus employed therein.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

(From the London Gazette, Aug. 30, 1859.)

949. G. Ashcroft. Hydraulic machines.

954. J. Glasgow and S. Hand. Circular motion.

967. J. Luis. Raising water. A communication.

992. Q. Beck. Stoves. A communication.

1008. E. Clark. Sewing machinery. A communication.

1020. P. L. M. Debain. Motive power.

1024. R. A. Brooman. Manufacture of cloth. A communication.

1025. J. Marshall, jun. Filtering fluids.

1036. A. W. Gadesden. Sugar.

1037. E. Humphrys. Steering.

1039. H. C. Hurry. Motive power.

1045. W. E. Newton. Nitric acid. A communication.

1048. R. A. Brooman. Paints and colours. A communication.

1049. R. A. Brooman. Steam boilers. A communication.

1050. J. H. Johnson. Fibrous substances. A communication.

1061. T. Lacey. Gas regulators.

1062. Sir T. T. Grant. Cooking apparatus.

1067. R. Harrington. Umbrellas and parasols.

1072. J. Wheat. Drilling machines.

1076. W. Corbett and W. Carmon. Furnaces.

1079. E. A. Porteus and W. H. Burke. Presses.

1107. W. Clark. Alkalies. A communication.

1129. W. Clark. Drills. A communication.

1259. E. Pasquier. Drying wool.

1318. T. Wilson. Fire-arms and ordnance.

1440. S. Levy. Coverings for the head.

1443. J. Luis. Gas burners. A communication.

1444. L. Barroux. Railroad.

1500. G. T. Bousfield. Winding. A communication.

1572. E. A. Wood. Raising and lowering boats.

1601. J. Luis. Washing wool. A communication.

1749. C. W. Smith. Electric telegraphs.

1774. W. Campbell and G. Worstenholm. Nails. Partly a communication.

1840. G. T. Bousfield. Vulcanizable gums. A communication.

1843. J. D. Bryant. Lime.

1872. J. Stuart. Nails.

1903. W. Wilson. Earthenware.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

PATENTS ON WHICH THE THIRD YEAR'S STAMP DUTY HAS BEEN PAID.

2006. B. A. Grautoff. 2023. J. Gregory.

and C. H. W. Albrecht. 2053. G. Anderson.

2007. T. Watson. 2102. C. Brook, jun.

NOTE.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office.

LIST OF MISCELLANEOUS TENDERS INVITED, AND ENGAGEMENTS OPEN.

The tenders and vacancies which appear in this weekly list are not repeated in succeeding numbers.

HARBOUR WORK, Scotland.—For the Elgin and Lossiemouth Harbour Company. Contractors are wanted for the excavation and completion of a new basin, and for building a sea-wall, according to plans, sections, and specifications prepared by J. Abernethy, Esq., C.E., London; to be seen at the Town Clerk's Office, Elgin; or at the Harbour Office, Lossiemouth. Tenders with Mr. Duff, Town Clerk, Elgin, noon, September 10.

RAILWAY, Ireland.—The plans, sections, working drawings, and specifications of the extension from Newtonards to Donaghadee, with branch to Bangor, of the Belfast and County Down Railway, are now for inspection at the office of the Company, Queen's Quay, Belfast. "The day for receiving and opening tenders will be stated in the specification," the advertisement says.

WROUGHT-IRON BRIDGE, Victoria Railway.—Tenders are invited for the girders of a wrought-iron bridge for the above railway. Specifications, 4 Abchurch-lane, and further information J. K. Brunel, Esq., 18 Duke-street, Westminster. Tenders to De Pass and Sons, 4 Abchurch-lane, September 6, before 3 o'clock.

ROLLING STOCK, Victoria Railway.—For 4 first-class carriages, 4 second-class and 1 break van. Specifications, 4 Abchurch-lane. Tenders before 4 o'clock September 12, to Messrs. De Pass and Sons.

RAILS, London, Brighton, and South Coast.—For the supply of 1,000 tons of double-headed rails, 75 lbs. per yard. Specifications and forms of the Storekeeper, Mr. W. Walker, Railway Terminus, Brighton. Tenders to Mr. Frederick Slight, Secretary, London-bridge Terminus, by 10 a.m., September 8.

WATER WORKS, Skipton.—For the construction of a Reservoir, Filter Beds, Grating Tank, Regulating Tank, Pine Water Tank, Bye Wash, and other works connected. Plans, &c., of Mr. T. Curley, C.E., Local Board of Health Engineer's office, Skipton. Tenders, Mr. Calvert, Skipton, Clerk to Skipton Water Works Company.

CAST-IRON SCRUBBERS, Burnley.—For the erection of 4 cast-iron scrubbers, with 15 inch slides, valves, force-pump, and connections complete, for the Burnley Improvement Commissioners. Plans and specifications at the Gas Works, Burnley. Tenders to W. M. Coultate, Esq., Burnley, Chairman, September 5.

WATER-PIPES, Cheshire.—The directors of the Wirral Water Works Company are prepared to receive tenders for the delivery of water-pipes, according to specifications for the townships of Oxtown, Tranmere, Prenton,

Rock Ferry, in Bebington, &c. Specifications, Mr. Cunningham, Engineer, 5 Cook-street, Liverpool. No date given.

SEWERING, PAVING, &c., Manchester.—For sewerage, levelling, paving, flagging, channelling, and completing the parts of 4 streets within the Newton district. Particulars, Messrs. Corbett and Baby, Surveyors to the Newton Heath Local Board of Health, Queen's Chamber, Market-street, Manchester, September 15.

STONE BRIDGE, Blackburn.—For the erection of a stone bridge across the river Ribbles, in the jurisdiction of the Blackburn and Preston Turnpike Road and Bridge Trustees. Plans, &c., with printed forms, Clerk of the Trustees, Sharrock Fold, Blackburn; to whom tenders, September 14.

NEW SEWERS, Derby.—Also the construction of flushing cisterns, side entrances, &c., in several roads and streets. Plans and drawings, Offices of the Local Board of Health, Full-street, Derby. Tenders to September 8th.

CEMENTWORK, Bacup.—For the draining, excavating, and boundary-walling at the new cemetery, Fairwell, Plans, &c., Office of Mr. S. Hall, Clerk to the Board, Irwell Terrace, Bacup, on September 12. Tenders.

FOUR COTTAGES, Staffordshire.—For the erection of four cottages at Gnosol, belonging to the trustees of charities. Plans, &c., at the school-house. Tenders, Rev. J. Phillips, Gnosol Parsonage, September 8.

BUILDINGS, Spaldington, near Hove, East Yorkshire.—For various buildings upon the estate of Sir H. Merryman Vavasour, Bart. Plans, &c., after Monday next at the residence of Mr. Carmichael, Spaldington; and a duplicate copy at 22 Backville-street, London, up to Sept. 6; afterward at 17 Tenant-street, Derby; at which two last-named places bills and forms, the architects being Messrs. Stevens and Robinson, of Derby and London. Tenders by noon, Sept. 12, to Sir Henry M. Vavasour.

SCHOOL AND MASTER'S RESIDENCE, Llanfair, near Aberystwyth.—Plans, &c., Rev. D. J. Jones, Vicar of Llanfair, or at Mr. Withers, Architect, 51 Doughty-street, London. Tenders to Sept. 10th.

PAVING, Ware, Nary.—The contract for a period of 4 years certain, commencing January 1, 1860. Forms and information, Steward's Office, Greenwich. Tenders, Sept. 8, at Greenwich Hospital.

MARKS OF DISTINCTION, Nary.—For supplying and delivering into Her Majesty's Victualling Stores at Deptford, Gosport, and Plymouth, all such marks of distinction for petty officers and leading seamen of Her Majesty's Navy as shall from time to time be demanded under a contract for 12 months certain, and further until the expiration of 12 months' warning. Patterns at the office of Comptroller for Victualling, and at the Victualling Yards at Gosport and Plymouth, where may be seen the recent modification of the conditions of the contract, to which particular attention is drawn. Tenders, Sept. 8.

ROAD SURVEYOR.—The trustees of the Yorker and Great Western Roads will elect a Surveyor to fill a vacancy that has just occurred, on the 14th inst., at two o'clock, at the George Hotel, George Square, Glasgow. Applications to the Clerk of the Roads, Glasgow, Sept. 14.

MANAGER FOR TAR AND ASPHALT WORKS.—For the country. One with a practical knowledge of artificial manure making will be liberally treated with. Address, Walmsey and Co., Advertising Agents, 4 Old Millgate, Manchester.

SETTER OF CARDING ENGINES.—Composed of rollers, clearers, and flats. A man with a knowledge of roving frames preferred. Victoria Mills, Parricroft, Manchester.

FOREMAN ENGINEER.—Competent to take charge of erecting and fitting, and assist in the general management of an engine works of about 40 hands. Address, in confidence, stating qualifications and terms expected, C. 30 Office of the Manchester Examiner.

ENGINE FITTER.—Accustomed to locomotive work. Constant employment. No club-man need apply. Address, F. 55, Office Manchester Examiner.

PRICES CURRENT OF METALS.

REMARKS.—A very moderate amount of business doing, with scarce any fluctuations in price.

LAWRIE AND HAGGER, Metal Brokers.

83 Lombard-street, E.C.

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, SEPTEMBER 9, 1859.

OUR SCREW SHIPS.

"THERE is," says the old proverb, "no royal road to learning," nor is there, we are persuaded, to excellence or worth of any kind. We nearly always estimate the value of any production of hand or brain by the amount of manual or mental labour which has been bestowed upon it. The capacity to toil and to endure is our human capital, and is the source of nearly all human success. Perhaps none are more sensible of this than literary men. They know it to be possible to spin out a few new ideas or facts into lines and columns, and even to reproduce old ones with some show of freshness; but they know also that, even commercially, the value of what they write is dependent upon the amount of useful material embodied in it. A new fact is the virgin ore of the journalist, which is made to assume a thousand forms, and serve a thousand purposes, as it passes on from hand to hand. But "all is not gold that glitters;" much base metal is turned to account by unscrupulous or ignorant workmen, and may long escape detection. We have instances of this constantly before our eyes in our periodical literature, especially with regard to scientific matters; and we think it our duty to notice a recent case, not only because it appears in a journal which has some pretensions to authority in the matters of which it treats, but because the article in question has been transferred to the columns of the *Times*, and may work mischief. We refer to a leading article which appeared in the *United Service Gazette* of the 3rd inst., on "Our Screw Ships." It is asserted that "we go on building and altering" our ships of war "without any visible improvement. Ships and engines are constructed at an enormous cost, and when completed we find no perceptible gain." To support this statement they say: "The Agamemnon, a two-decker, one of the first ships built for the screw, steamed 13 knots with 650 horse power; the Mersey, a single-decked ship, nearly 100 feet longer, and with 1,000 horse power, goes very little faster, while the Orlando, another single-decked ship, 50 feet longer than the Mersey, with power working up to 4,000 horses, has only been propelled about a half knot more than the Agamemnon. On the other hand, we have the Himalaya doing 16 knots with 700-horse power, only partially exerted."

Now, this is an entire tissue of mis-statements. The Mersey is 70 feet longer than the Agamemnon, instead of 100 feet; and the Orlando is exactly the same length as the Mersey, instead of being 50 feet longer; so that while the Orlando is made out to be nearly 150 feet longer than the Agamemnon, she is really but 70 feet longer. The Agamemnon of 600, not 650, nominal horse power has, we believe, never obtained a greater speed than that recorded in the Admiralty Tables, recently published by us, viz., 11 knots, while both the Mersey and the Orlando have reached 13½ knots or 15½ miles per hour. Again, the nominal horse power of the Himalaya is 700, but when the engines were worked up to 2,014 horses power the speed was 12·922 knots instead of "16 knots with 700-horse power, partially exerted!" With the piece of gossip that the "General Admiral is said to go 15 knots," we have nothing to do; we can only say we do not believe it.

After making these remarkable statements,

the writer goes on to say, "The impression left in our mind by the experiments on board the screw frigates is, that there is a considerable excess of power developed, which is, in fact, wasted, and that the waste retards rather than accelerates the speed." "We see no reason to doubt that the Orlando would attain a higher rate of speed with 500 or 600 horse power, moderately used, than with 1,000." How a sensible man could write such nonsense as this, we are at a loss to conceive. Is it necessary to tell any of our readers that the power of an engine can be reduced at a moment's notice, as much as ever we please? Why, the ordinary steaming of the Orlando, and of every ship in the Royal Navy, is performed with only one-half the real power of the engines, and it is only on extraordinary occasions that their full power is called out. The officers of the ship may always discover what effect a reduction of engine power would have upon her, even taking into account the reduction in weight; for the difference in the draught of water caused by taking out the coals will generally be much greater than by any reduction which could be made in the weight of engines; so that by regulating the quantity of coals in the bunkers they can assume what conditions they please. While we possess such a simple means of experimenting, and while, moreover, we have such a mass of experiments already made, it is idle to discuss such cases as that of the Vectis, which, we are informed, "would only steam 14 knots with 400 horse power," but "goes 14½ with 250." For anything we know to the contrary the effective horses' power developed by the small engines, and therefore the quantity of fuel consumed, may have been greater than by the large ones.

There is really no ground whatever for the assertion that we find "no perceptible gain" in our ships of war. The speed of the Mersey and Orlando is, reasoning from the Agamemnon, as high as could be expected when the difference in the immersion of the screw is taken into account. According to the ordinary theory, which is known to be defective, the indicated horse power in the same ship, or in similar ships, varies as the cube of the speed. We should therefore conclude that if 1,839 horses' power gave 11 knots in the Agamemnon, as they did, 4,000 horses' power would give a little over 14 knots. No one at all acquainted with the subject would have expected to realise this in the Mersey and Orlando, and we believe the Admiralty are very well satisfied with the results they have obtained in those ships.

THE BUILDERS' STRIKE AND
LOCK-OUT.

It must be with some degree of diffidence and caution that an impartial writer will treat such a question as the strike in the building trades which for some time has engaged public attention. In the first instance, it is a question which mainly regards the masters and the men, and can be decided by them alone. Hitherto the law has pronounced neither to be aggrieved. Both parties may be presumed in practice to be the best judges of their own position and interests. And consequently there is no occasion for any violent intermeddling on the part of the public or of the press. Newspaper articles such as we have lately seen—flippant and somewhat arrogant in their tone, upholding capital on principle, and blaming the workmen on the inadequate grounds that he disturbs the convenience of his late employers in adopting what he considers the most effectual means of advancing his own interests—can only serve to irritate and strengthen the mutual opposition. They may harmonize with the ideas of "order"

held by a class whose sympathies are not extended to the worker, whether he be right or wrong in his struggle against capital; but they must lower the press in the eyes of many men who perforce have had this theme before them during long weeks of anxiety—perhaps of privation. In poverty and hunger these men have stronger appeals to urge the present expediency of submission than any they can receive from the *Times* or from the *Globe*. We believe they are ready to learn their own interests from those who are capable of teaching, and who they have reason to think will advocate the same. But they must see, in presence of past experience, the absurdity of condemning without qualification the course they have followed, or of accusing them of folly upon other premises than that of ultimate failure. Nor can this premise be assumed without contradiction. Strikes have not always been unsuccessful, and rumours of strikes have not always been without benefit. So long as the present relations between capital and labour remain unaltered, the strike of the workman on the one hand, and the discharge of the labourer when no longer required on the other, must be converse and necessary phenomena in the history of supply and demand.

Leaving all other questions of expediency out of the question, it is evident that the ultimate result of success or non-success can alone decide the policy of this particular movement. To tell the working men that they are wrong in their policy before this result is proved—before even it can be fairly asserted one way or the other—is a presumption and a fallacy. We believe ourselves that "strikes," so detrimental in themselves, are necessary only in rare and exceptional cases. In the present instance, if unsuccessful, it will be evident that the strike was not called for by the conditions of the labour market. But, on the other hand, the principle which has led to this manifestation is probably more conducive to the ultimate interests of the employed than would be a tame submission to the dictates of capital. The value of labour, like that of any other commodity, must be fixed by mutual agreement between the buyer and the seller; and this agreement cannot always be arrived at without dispute. When the true value cannot be recognized, and a misunderstanding arises, the difference of opinion may be prejudicial to both buyer and seller; but less so to the latter than if the question had been left in the hands of the former alone. Nor are there any grounds to make this difference of opinion the subject of a quarrel, or the occasion of vindictive feeling. It is to be observed, in opposition to the argument of a distinguished contemporary,* that what in this case occurs individually may also occur collectively; for competition alone can by no means always determine the actual value of a commodity, and, indeed, often tends to lower the price in undue measure.

Among those who would insist upon the subserviency of labour to the dictum of capital, there may be many who consider it as a necessary principle, and conducive to the interests of the employed. A portion of those who hold this view may be capable of sympathy with labour, and willing to recognize its claims. But these cannot go so far as to ascribe moral wrong to the artisan who would raise the commercial value of his labour by carrying out in practice the opposite opinion. Those who would meet the assertion of a natural right with the opprobrium bestowed upon the disturbers of "order," or the disciples of democratic notions, must be influenced by the selfish and illiberal prejudice of class, which is equally incompetent to form an unbiassed judgment and unworthy to take part in a discussion involving the interests of

the working classes. The sympathies of such men must ever be adverse to the cause of labour, and their opinion is worthy of little respect or consideration. If sympathy, instead of calm and practical discrimination, were called for, it should be due to those men who are engaged in an unequal struggle to maintain their convictions, rather than to the possessors of that capital which has been accumulated by means of their toil, and which, entrenched in the "Three per cents," can cry—*Vae victis*,—starved be the vanquished!

The above considerations have, we think, been too much neglected in the discussions which the press has set up respecting the present labour dispute. A former article of ours will have been sufficient to show that we are far from sympathizing with the despotic tendencies of trades' unions, and other like associations. At the same time we should grieve to have it thought that we are insensible to facts of an opposite complexion; for we are fairly persuaded that no good can come from any advocacy in which either master or man is denied what is due to him.

THE WOOLWICH EXPERIMENTS ON CAST IRON.

A "BLUE BOOK" nearly two inches thick, consisting mainly of complicated tables, is not a pleasant thing to write upon; but such a book is the topic of the present article. We cannot hope, therefore, to make ourselves particularly agreeable in what we are about to say; at the same time we hope, by aid of the Report before us, to make ourselves instructive.

On the 5th of June, 1856, Lieut.-Colonel F. Eardley-Wilmot, superintendent of our Royal gun factories, wrote to the Right Hon. W. Monsell, M.P., Under Secretary of State for War, as follows:—"I beg," he said, "to call attention to the desirableness of enlarging the series of experiments as to the best quality of iron for cannon. The question is one of great importance as regards the public service, and the improvement of an important branch of British industry. A true and valuable result can only be arrived at by the possession of satisfactory data; we are now in a position to make the necessary experiments. The cost of procuring the sample of iron as proposed in the accompanying advertisement, will be small compared with the magnitude and value of the results, in a national point of view. I beg to suggest that the enclosed advertisement be put in the public papers herein detailed, and that the replies and communications be forwarded to me when received. By this means Her Majesty's Government will furnish for their own use, and for the nation, a series of data of the highest value and importance." The "advertisement" alluded to in this letter was published in the public prints on the 9th of June, 1856, and announced that the inquiries would comprise chemical analyses, specific gravity, tenacity, torsion, transverse strain, compressibility, impact, rendering, and elasticity. Samples of not less than five cwt. of pig iron, with a small quantity of the fuel, flux, and ore employed, were to be sent in. A statement was also to accompany the samples, giving all particulars, and specifying that the sample of iron was of the first or second melting, as the case might be; also that the samples had been taken at random, and that similar iron can be produced in quantity. None that had been melted more than twice was to be received.

A great number of ironmasters responded to the invitation thus given, and a series of experiments, of an extensive and laborious character, was at once commenced, under the superinten-

dence of Colonel Wilmot. The specimens have all been tested by Mr. M'Kinlay (the proof-master) and his assistants, who conducted the trials. They were roughly prepared in the factory, and accurately finished by Robert M'Kenzie; the specific gravities were taken by George Simm; and the necessary computations were by Robert Smith, computer. The subject is one of considerable interest and difficulty; and the publication of the results will, it is justly hoped, be followed by the careful examination of them "by many of those able men whose writings on subjects of cast iron, and the strength of materials generally, are well known."

The term "cast iron," as describing any specific material, does not (we are told in the report) convey to the mind of those connected with such experiments any more positive quality than what may be gathered from the use of the term "wood" in speaking of that material. The remarkable range of the various qualities of different samples is scarcely more marked in the latter than in the former; and, in addition, the same iron treated in a different manner, as regards the apparently simple process of melting or cooling, assumes a different character. The general result of a considerable number of experiments made on this point is shown in the Table given in the foot-note below.* In the Woolwich experiments there has been no intention of ascertaining any data relative to the most suitable mixtures of various brands of iron, or of making experiments as to the treatment of any particular iron with reference to improving its quality; the object has been simply to ascertain which quality as purchasable in the market, or when specially supplied, is suitable for the particular purpose of making cannon. The iron has all, therefore, been treated in a precisely similar manner, and with few exceptions in the same furnace, which was kept free for the purpose. The pigs were broken, and where a variety of appearance was found turnings of each were mingled together and examined as a mean sample for analysis. And here we are at once met, as the Report very properly says, by questions which indicate the magnitude of this inquiry, if carried to its full extent. Does not almost every variety of iron require some treatment peculiar to itself? and, to effect an object with any particular iron, must there not be a definite dimension suitable to that iron? It is thought that it is so; and that in a gun, for instance, the form and dimensions offering the greatest strength with one iron, are not those best suited to another.

The results already obtained by various experiments on the subject of re-melting cast iron are well known, and have been repeated at various times in the works of the War Department; when, however, the experiment is made

* TABLE showing the comparative qualities of Cast Iron; also the ratio of their strength (deduced from the general mean) as shown by the different tests.

	Specific Gravity of 850 Specimens.	Tensile of 850 Specimens.	Transverse of 564 Specimens.	Torsion of 276 Specimens.	Crushing of 273 Specimens.
Maximum.....	7.343	34,279	11,321	9,773	140,056
Minimum.....	6.822	9,417	2,586	3,705	44,563

Ratio in terms of the Crushing.....		.255	.078	.066	1.000

with large masses of iron of several tons, the effect produced is not so marked. It would appear, we are told, that without any considerable diminution of the impurities in the metal, as silicon, sulphur, and phosphorus, a considerable increase of tenacity and specific gravity can be obtained. The graphite is partially expelled, and some of it is converted into combined carbon, and the contraction and crystallisation is more energetic and complete. This combined carbon can, it is thought by some, on again re-melting the mass and very slowly cooling it, be re-converted to graphite, rendering the iron soft and fusible. This is undoubtedly the case with the product of the refinery process known as "metal," the use of which, on this principle, formed the subject of a patent, by Dr. Price, in 1856.

There is a point not, probably, accurately determined, at which the maximum hardness corresponding to the maximum tenacity may be found. In an iron cannon there is, however, required an elasticity in addition to other qualities, when these qualities are not in excess to such an extraordinary degree as to render the mass so strong and rigid as to obviate any danger of disruption. It has been found in the various experiments made at Woolwich, that in most cases where the specific gravity is 7.3 or upwards, the metal is unsuited to gun purposes, on account of its hardness and want of elasticity; while the same iron, treated in the furnace for a shorter time, and being when cast of a lower specific gravity and less tenacity, would have resisted more satisfactorily the explosion of the powder. "In the case of a cylindrical round bar 26 feet long and 7 inches diameter, cast vertically, the following specimens were taken. The mixture is similar to that used at the time for making guns, and was melted in a single furnace charged with 33 cwt. 2 qrs., and occupied 2 hours 15 minutes in melting. Two discs in immediate contact with one another, each furnishing two tensile specimens, were cut off from the top, the bottom, and the centre, i.e., at intervals of 11 feet 11 inches asunder."

	Tensile.	Specific gravity.		Tensile.	Specific gravity.
Top.....	29,382	7.251	Bottom.....	26,594	7.325
".....	27,872		".....	27,122	
".....	31,266	7.183	".....	29,985	7.323
".....	30,587		".....	30,889	
Centre..	29,231	7.251	Combined Mean:		
".....	26,218		Top.....	29,778	7.217
".....	27,499	7.325	Centre.....	27,650	7.263
".....	27,649		Bottom.....	28,648	7.324

The effect of the fluid pressure as regards the density of the metal is here sufficiently well marked; but the tenacity is not increased.

It would require a longer series of experiments than the Woolwich authorities have had time to institute, to establish accurately the relation between the amount of fluid pressure and the resulting tenacity and density. The result here given would appear to be in conformity with the opinion that increasing the length of the dead-head does not add to the resisting power of the metal when used for a gun, all that is required being to afford an ample allowance for feeding in shrinking, in consequence of the strength not being due to pressure or condensation, but to the contraction and crystallisation of the mass. In bronze or brass gun metal, the material being of a compressible character, a very decided result is obtained, as is shown in the following experiment upon specimens cut from the base, the muzzle, and the dead-head of a six-pounder brass gun, having about 30 inches in vertical depth between each:—

	Specific gravity.	Tensile.
Top	8.539	35,000
Centre	8.545	38,704
Bottom	8.814	49,401

The most decided features to be observed in the results obtained in the recent experiments are the universal and very marked superiority of the bars in the cases where they have been cast horizontally over those cast vertically; and the superiority, but in a less marked degree, of the bars cooled quickly over those cooled gradually or slowly. This is almost universally found to be the case in the experiments hitherto made with a portion of metal taken from the dead-head, close to the muzzle of the gun, as compared with the bar cast at the time of making the gun. The contrast as regards appearance is equally marked. In the bar, a close, grey, rigid appearance; in the dead-head, a large grain with graphitic masses joined or cemented together with a whiter and harder material.

Certain supplies of iron ordered in consequence of the results obtained in these experiments have, on examination, unfortunately given results differing much, both chemically and mechanically, showing superiority in some cases and inferiority of a marked character in others. The demand for the manufacture of iron ordnance, and "the necessity for the supply of a certain number to meet what is expected in this country of a new Government establishment," has, we are significantly told, prevented such various experiments being made as are desirable. At a new Government foundry on the Continent, established about the same time, two years were allowed for experiments before a "supply" was demanded. It would appear that a great deal is still to be done on this subject, and that we are only now at the commencement of vast improvements in the manufacture of cast iron and cast steel. Some very fine results have been obtained from cast material prepared by Mr. Bessemer, which promise well; and, generally, the attention of those connected with the manufacture and use of iron is being directed to the subject.

It cannot be too strongly urged, says the Report, that the possession of a machine such as that in use in the Royal gun factories would greatly assist inquiries. A drawing of it is given in the United States "Reports of Experiments on Metals for Cannon," Trübner & Co., Paternoster-row; and the use of it, with several additions, can be seen at the Arsenal. The manufacture of similar or improved machines, and the distribution of them through the country, would be attended with great results.

In the above remarks we have, as will be observed, had to draw largely upon the official Report, and even with the aid of this we must still leave much unsaid respecting the results of these elaborate experiments. For the deduction of information from those results we, like the Woolwich authorities, look to those "able men" before referred to. On another page, however, we have the satisfaction of printing a very able and interesting paper on the chemical results of the inquiry, from the pen of Mr. Abel, the accomplished chemist of the War Department.

THE PENNY PRESS AND THE NEW COINAGE.

THERE can be no doubt that the penny press of this country is effecting a vast amount of good. It is adding—imperceptibly, perhaps, but not the less certainly—to the general intelligence of the community at large. Politically, its articles—we refer more especially to the Metropolitan section of the cheap press—are written in an enlightened spirit, and where they

may not be taken as infallible guides to the true doctrines of political economy, are at least suggestive and valuable aids to the study of that science. As promoters of sound moral sentiments—with, possibly, some occasional exceptions, the results of inadvertency—the penny newspapers of London may be pronounced faultless. As media, too, for introducing to classes of society who would never otherwise have the advantage conferred upon them, the opinions and the deductions of men of science, and with the records of discoveries and inventions resulting from their theories and their labours, there is much reason to be satisfied with them. Their published extracts from expensive and first-class publications, and their reports of the proceedings of learned societies, notes of whose doings would never otherwise extend beyond the immediate circle of savans in which they take place, are invaluable to the public; and on all these accounts and on many others we are pleased to be able to bear testimony to their value.

This general approval of the spirit and conduct of the penny press, which we unhesitatingly and conscientiously give, will guard us from having imputed to us hostile motives when we take the liberty of criticising unfavourably a particular article in the *Daily Telegraph*—we believe the oldest journal in the category. As the *MECHANICS' MAGAZINE* will be acknowledged to have been the first mover for a reformation of the inferior coinage of the realm, and as preparations are, according to Mr. Gladstone's recent statement in the House, being made to accomplish that reformation, it will be accorded to us to speak out when what we think fallacious views respecting the principles upon which the new coinage of bronze *vice* copper should be based. In the *Daily Telegraph* of Saturday last there appeared a leading article upon the projected change, wherein the writer, with pen more trenchant than just, hurls indignant epithets at the entire metallic currency of the kingdom and those who created it, and denounces the coining improvement as a cheat! "If the present idea be carried out"—that of issuing small coins of bronze—"the coinage will be simply worth nothing at all. In fact, it will be a mongrel metal, glittering and worthless, like the civilisation it represents." These are harsh assertions. Are they borne out by reason or experience? We imagine by neither. We have explained before that ever since the year 1799, when the last coinage of what are called the "ring pence" of George III. were struck at Soho, the copper coinage of England has been completely on the token system. Ever since that period—with the exception of a coinage for Ireland of more reduced weight still—the pound avoirdupoise of copper has been coined into twenty-four pence, and the subordinate coins in the same proportions relatively to their value, namely, half-pence 48 to the 1 lb., and farthings 96. This makes a ton of coined copper worth in round numbers £224. Does the *Telegraph* writer require to be told that the average market price of "tile" copper, of which those coins have hitherto been manufactured, has not been over £100, and that consequently neither he nor any of his fellow-subjects, even though they may have had the satisfaction of having their pockets weighed down by the "clumsy slabs of copper" of a former generation, ever possessed copper coins whose intrinsic value and weight were equal? The whole of the copper coinages of the last three reigns were therefore palpably tokens of value and nothing more; and we certainly should not expect to find a pair of scales and weights placed on the counter of the *Telegraph* office to test the pennies tendered in exchange for its valuable and broad

sheets. A Victoria penny weighing two-thirds of an ounce is, we doubt not, as acceptable in exchange for a *Telegraph* as one of George III.'s "cart-wheel" pence, weighing one ounce. What becomes, then, of the charges of "innovation" and "impotence," bandied freely in the article complained of?

Will it not be infinitely more convenient that three thousand tons of metal should—in the form of, we trust, beautiful coins—represent the six thousand tons of the "ugliest coins in existence," which now circulate throughout the British Isles? Is there any reason why "slabs" of soft and nasty copper should be carried to and fro when neat, hard, and cleanly discs of bronze would answer every purpose and be infinitely more convenient? If in the one case a ton of copper, costing in the market say £100, is coined into £224 worth of pence, half-pence, or farthings, in the name of common sense we ask how will the public be losers by coining a ton of bronze whose value in the market is taken at £110, into £448 worth of coins? The profit on the coinage will be greater, we admit, but the Mint is a public institution, and the public must inevitably be gainers by the operation. If we were dealing with private manufacturers the case, of course, would be widely different, and the strictures of the *Daily Telegraph* would be justified. As it is, the inferior coinage of the realm is got up for public convenience at the public expense, and the problems to be solved in the renewal of it are, the best metal, the most portable forms, and the handsomest in appearance. The weight of the individual pieces is clearly a matter of indifference, and if they be made more economically and more durable than the "cart wheel coinage" of George III., why so much the more advantageous for the people who in the shape of Civil Service Estimates must pay all the expenses attending their production.

Again, if our friend of the *Telegraph* were to induce the Chancellor of the Exchequer to adopt his plan of giving equal weight and value in the new coinage, what would be the consequence? and that, probably, before the coinage was a month old. Why, that a rise of £10 per ton in the market price of copper—and fluctuations wider are of constant occurrence—would consign the whole of the newly-minted money *sans ceremonie* into the furnace of the manufacturer—and we should all become in the "twinkling of an eye" literally penniless. But enough must have been said to convince our readers that this portion of the plan of the *Telegraph* writer would *never* answer. It is painful to be obliged to dissent also from almost all his other propositions.

For example, as touching the device to be imprinted on the forthcoming coins, we cannot think that in imitation of the ancient "Romans" we should give them impressions illustrative of the progress of our arms and of our great achievements in various quarters of the world. It would be difficult to convince us that "symbols of captured Lucknow and Delhi"—places whose names are better forgotten—of the "annihilation of Sebastopol, of the conquest of Scinde and Pegu, of the colonisation of Australasia, and a hundred other events," should figure on the new coins. We are rather disposed to think, on the contrary, that such a proceeding would lead to inextricable confusion, and open a door for the wholesale introduction of counterfeits. A uniform, chaste, and appropriate device, characteristic of the insular position and maritime greatness of the kingdom governed so well by our Queen, should, in our opinion, decorate one side of each piece of the new money, whilst the "image and superscrip-

"tion" of Her Majesty should enrich the other.

As regards our friend's criticism of the present gold and silver coinages, there again we are at issue. We never saw "something meant," we believe, to be a cross flinging about its "arms like the fans of a windmill on one side" of our silver pieces," although the writer of the *Telegraph* may. As to what the "mean and "pitiful" designs complained of may be we are equally in the dark. Of the engraving of the coins generally, although others may think it "abominably executed," the Wyons, whose work it is, may rest assured that there are those, whose opinions are worth having, too, who say that on the whole it is excellent.

The reckless remarks of the journal in question on this particular subject are so exceptional to the general care and truthfulness displayed in its articles, that we are compelled to notice the matter.

WHERE WILL THE BRONZE BE COINED?

UPON further examination and reflection it seems to us that one of the very first questions relative to the new coinage which should be considered by the Chancellor of the Exchequer, is that of the capabilities, mechanical and otherwise, of the Mint. A tardy and gradual introduction of the bronze coins would produce a mischievous effect. Already there are innumerable representatives of copper tokens floating in the channels of circulation, and which pass current simply because they approach the size of the orthodox pence, halfpence, and farthings. To add to this "variety," which is the reverse of being "charming," by slowly and timidly comingling with them another set of specimens, would be but to increase the existing confusion. The reform adopted and to be carried out by the Government to be effectual must be rapid. Unlike political reforms, which are usually of very, very slow growth, this must be sharply and suddenly matured. There should be in the Mint stores a large accumulation of the miniature bronze pieces before any are issued to supplant the giant copper coins. A simultaneous publication of the one and withdrawal of the other might then be made without difficulty or annoyance. In London, and, by aid of railways, in all large towns of the kingdom, the exchange of bronze for copper might go on at once, and within a week millions of beautiful light coins would be jingling in the pockets of the people in lieu of the absurd "slabs" of metal which now weigh their pockets down and wear them out. It is evident, indeed, that a quick transformation must be effected. Mr. Gladstone cannot fail to perceive its necessity, and probably is adopting means for its accomplishment. But he must inquire primarily, one should think, into the productive powers of the Mint. At all events, we have done so, and our conclusion is, that they are at present inadequate to the "great occasion." For the manipulation of all the gold, silver, and inferior metal coins for England and many of the colonies the Mint possesses only six pairs of rolls, a dozen cutting-out or punching presses, thirteen of the Cotton-Napier weighing machines, and eight Soho stamping presses. Now, taking the maximum rate of production of these latter, as given in the Parliamentary blue-books by Mint authorities, at 240,000 coins per day, how long would it take to strike off five hundred millions? We need not stop to answer the question; it is clear that by devoting the whole resources of the money factory to the creation of the new money it would still be a work of many years. When it is known additionally, too, that the Bank of England is incessantly demanding gold

and silver coin, and that from the fluctuations of the continental markets and other disturbing causes at home, much has frequently to be struck off in a short time, it becomes obvious that the Mint would be as unable to accomplish the work required of it as would the stage coaches running five-and-twenty years ago to convey the passengers of the railway trains of to-day. Doubtless this fact is patent to the Chancellor of the Exchequer, who is no unworthy disciple of "Cocker;" but how does the right hon. gentleman mean to remedy it?

A private manufacturer, whose business—were it the making of hats, or of money, or both—had outgrown his premises, would inevitably increase, if he could, his facilities for doing work. Surely the same course will suggest itself to the Treasury and the Mint people. Like other manufacturing, the Tower-hill establishment served its purpose and met all its demands for many years, but, like them, it feels now the pressure of a new state of things, and it must be expanded so as to divide that pressure over a wider area. The Californian and Australian gold discoveries have, as the Mint returns to the House of Commons demonstrate, served to keep the stamping presses at work for a considerable part of the past nine years; and although the Sydney Mint relieves it to some extent now, yet that extent is barely appreciable. There are only two presses, we believe, at Sydney, and their production is small and exclusively colonial. Advancing commerce, increasing trade, widening speculation, and growing emigration, make it certain that more and more of coin with the British stamp upon it will be wanted. Why, then, is there any supineness in observing the "signs of the times," or in preparing for the duty to be done? Once the "Great Western" steam-ship was considered a marvel of ship-building and engineering skill, but what was she in comparison with the "Great Eastern," which will presently astonish our Transatlantic cousins? Progress in art, progress in science, progress in mechanical skill and mechanical devices, are the rule of the day, and why should Her Majesty's Mint prove an exception to the rule? Why should that numerous body of soldiers and policemen whom one sees "on duty" at the portals of the money factory appear to shut out from it mechanical improvement, and to roll back the tide of scientific invention? Is the area of ground inclosed by its boundary walls insufficient for the increased plant of machinery requisite to deal with the new coinage. If so, and the purchase of more property adjoining it is impossible, why then the sooner a migratory movement of the whole "concern" takes place the better. If the Mint as it stands is not capable of meeting the wants of the time, and is not large enough to receive from the engineering works of London or elsewhere the means and appliances which would make it so, why the sooner its site is made over to the dock company for a great warehouse the better. New machinery of improved character, and a building of larger dimensions, might soon be found for Her Majesty's coiners, and England might boast a national Mint competent to coin all the national monies. Seriously, it is not creditable that the demand for money should have outstripped the Mint's producing power—as our witness, the blue-book, proves it has—and it is urgent that Mr. Gladstone takes steps to mitigate the evil. Of course, it will be said, Well, there is private enterprise to fall back upon, and contractors at Birmingham or Manchester will be found ready, for a sufficient "consideration," to erect rollers, punches, and other machinery for carrying on the coiner's art and producing money at any speed. Yes,

we are aware of that; the manufacturers of Birmingham especially are a go-a-head people, but that is not quite the thing. A little of the "go-a-head" principle must be instilled into the Government mind. Thirty thousand pounds, *vide* Civil Service Estimates, are voted annually for the expenses of the Mint, including coinage, and if, as we believe, without an augmentation of any but the dead stock—the mechanical plant—it can be made to do all the work of the country, there can be no use in calling in contractors' aid at all, and the reformation of the coinage should begin with a reformation of the Mint.

In 1810 the establishment was as efficient, speaking of machines, as it is in 1860. Half-a-century has not added to its stature, whilst all around it has grown to majestic proportions. Calcutta, we are told, will shortly be armed with twenty-four stamping presses—twelve of them being of much improved construction, and each capable of stamping twice as many coins per minute as those at the Mint. Why should the Indian outstrip and eclipse the Home Empire? Let our ministers look to this; it is of importance, and the national credit is involved. Either no contract work in coining, or *all* contract work seem to be right; but money-making being so delicate a matter, and in the hands of contractors so likely to lead to serious irregularities, it seems to us that it should be retained jealously in Government hands.

DECIMAL COINAGE.

WE observe with much satisfaction that the "International Association for obtaining a Uniform Decimal System of Measures, Weights, and Coins," will hold their fourth general meeting at Bradford, on the 10th of October next. The noblemen and gentlemen comprising this society voted a resolution on the 28th November, 1855, to the effect that the "adoption of a uniform decimal system of measures, weights, and coins would be conducive to the manufacturing and commercial prosperity of the United Kingdom," and of many other benefits; and it must be permitted us to say that there is good ground for believing the resolution to be based on truth. The indefatigability with which the members of the Association have devoted themselves, at home and abroad, to the investigation of this important subject makes it certain that the Bradford meeting will be of great interest. We shall have the opinion of scientific men of all countries upon the decimal system, whilst there can be no doubt that Lord Overstone's adverse report will receive some attention at the hands of men well qualified to detect any sophistries or fallacious arguments it may contain. The names of Richard Cobden, William Ewart, William Fairbairn, Esq., C.E., and the Right Hon. Thos. Milner Gibson, figure amongst others as members of the Council of the International Decimal Association; and with these sturdy champions to support the decimal plans of measurement, weight, and value, we think that some little wordy fighting must take place before those plans are abandoned. It will afford us sincere pleasure to observe the progress made by the Association, and to endeavour to obtain for it a fair hearing, and for its propositions due consideration.

The *Gazette des Chemins de Fer* announces that a new break for railway trains has been invented by a M. Rigolier. From trials made it appears that a carriage driven at the rate of 20 kilometres per hour did not run more than 10 metres after the break had been applied; and that at a speed of 65 kilometres per hour it only ran 30 metres. It was also found that a locomotive could not drag M. Rigolier's waggon when his break was applied to the wheels.

THE GREAT EASTERN.

Sept. 7, Noon.

at ship having cast anchor off Purfleet at Erith and Gravesend) we can do no ve think, than gossip for a few minutes readers (for one can only gossip on ship- expecting the event which has kept both of the Thames thronged with cheering creatures for several hours this morn-

ring been our good fortune to receive one ery few invitations issued for this passage Great Eastern down the river, we embarked at "by the light of the moon," and found ship really was to undertake the passage, permitting, early to-day. In both en- ms all was ready for the purpose; the last ge-loads of stores were alongside, and were up-ly run on board by the steam cranes; ling was completed, as far, that is, as it ended to coal at Deptford; the rain and f the day had subsided; and the captain sed that nothing short of a gale would e departure of the morning.

sion was thus afforded for speculation upon ects we had of getting well down the -day, and this speculation we quietly pur- iple pacing the "great deck" (in a very mixture of moonlight and starlight) till ars grew nearly to their largest. As for apprehension we had, first, the fact veral very awkward bends and shallows present themselves almost as soon as our gs were slipt; and secondly, we had the fact that on the first trial of a stupendous ent mischances and miscarriages of some ay usually be looked for with confidence. o knew that the engines of our ship were unprecedented size, and were really about ut upon their trial for the first time. On or hand we knew that in Mr. Atkinson we o possess the skilfullest of pilots—in t Harrison the ablest of captains—and in jneers on board some of the cleverest prac- ion of the day. We further had the satis- of learning that the working of both the and the screw engines were to be placed the personal control of Mr. Scott Russell, him alone. This last arrangement was ted to inspire great confidence, because no old possibly have a higher sense than Mr. of the importance of handling the engines ly on this great occasion, and no one could warmer interest in their successful opera- On the whole, therefore, we "turned in" ed with our anticipations of the morrow's

result, thus far, has amply justified our ex- ons. By six o'clock this morning we were t, and found good reason to expect an early

By half past seven the tugs had hold of us, orings were slipt, and amid many cheers the r moved off. Without the slightest mishap, aot without a stoppage, this huge structure en brought in three hours to this spot, she has room to swing with the tide, and herself "at home," for the first time. From ment of starting, all eyes have been turned he pilot, the captain, and Mr. Russell, the rmer of whom have performed their duty he paddle-boxes as usual, while Mr. Russell pt himself stationed at the engine-room phs, upon the paddle-bridge, working the gines conjointly or separately, as seemed him—always, of course, supplying the required by the pilot. Neither engine has, r, run beyond very low velocities. Twenty fons per minute is, we believe, the greatest hich the screw engine has been allowed to and the paddle engine has been limited to seven or eight. It is no part of the pro- s' present purpose to attempt anything like

a trial of speed. The first thing is to get the ship safely out of the Thames; the next will be to get her comfortably round to Portland. After that she will start upon her "trial trip," and then will be the time for putting her to all necessary tests.

The experiment of to-day has sufficiently shown that the practical handling of ships of this im- mense size will present no great difficulties. Careful observation has enabled us to assure our- selves that, at low speeds, at any rate, the Great Eastern will steer well. Whether a high speed will interfere with her excellence in this respect can hardly be said; let us hope not. Then, as to the communication of the captain's instructions along her great length, very little difficulty has been experienced, notwithstanding the intricacy of the navigation in this instance; indeed, the only difficulty that occurred was that of getting the tugs a-head to do exactly what was required in all cases; no obstruction whatever interfered with the guidance of the helmsmen. Nor is this owing to the adoption of Mr. Lungley's admirable steering-signal apparatus, for through an error in the arrangement of one of the parts this will not be placed at the captain's service until to-morrow. The apparatus will, however, reduce this part of the vessel's management to the simplest form possible; for by it the captain will be able to speak to the eye of the helmsman—no matter how far off he may be—all but as quickly and distinctly as he could speak to his ear when at his side. We hope to see the apparatus in operation on our way to the Nore to-morrow.

We must not omit to mention the admirable precision with which Mr. Saffield's engine-room telegraphs have worked to-day. We have made them the objects of our special observation, and must say that their operation has been most satisfactory. In addition to our own testimony we may also add that of Mr. Scott Russell, who, as we have already said, worked them himself throughout, and who has subsequently assured Mr. Saffield that they have given him entire satisfaction; have proved themselves, in a word, "reliable."

To-morrow, the weather being moderate, we proceed to the Nore. We shall there, probably, have another opportunity of reporting progress, but not, we fear, in time for our next number. The ship, and all in whose hands she now is, deserve success, and we sincerely wish it them.

Thursday Noon, Off Southend.

We are now running down to the Nore under engines at "half-speed," the paddles making 8½ revolutions, and the screw 28. The theoretical speed of the ship (neglecting slips) is therefore about 13 knots; the real speed is 2 or 3 knots less probably, as the screw and wheels are insufficiently immersed to produce any near approximation to the theoretical result. The crew and company have saluted the ship, giving also three cheers, and one cheer more for Mr. Scott Russell and also for Mr. Brunel. All on board are delighted with the complete success that has thus far attended the ship's progress.

[We have at the last moment received another communication from our colleague (dated from Sheerness), stating that the ship ran down Long Reach most handsomely after the tugs were cast off. There is scarcely any perceptible vibration produced in the ship, except near the stern, and even there it is but very slight. She will have started for Portland before these lines appear.]

The following table, giving the theoretical speeds of both the paddles and the screw, graduated according to the number of revolutions made in each case, will be interesting. Experiments made this morning show that these theoretical numbers may be taken as practically correct, the slips in the two cases balancing each other:—

THE CHEMISTRY OF CAST-IRON.

By F. A. ABEL, Esq., Chemist of the War Department.

THE following paper on the "Results of the chemical examination of iron, and the materials employed in its production," is taken from the blue-book on cast-iron which has just been issued, and which is discussed in a leading article on another page of this Number.

A special report has been drawn up on the result of the analytical examinations of each set of samples received from the various works. To facilitate a comparison between the composition of the irons, ores, &c., tabulated statements have been prepared of the following description:—

Table I. embraces the numerical results obtained in the examination of the samples of iron.

Table II. exhibits the per-centages of the most important constituents of the various ores; and,

Table III. includes, similarly, the principal results obtained in the examination of the fuels and fluxes.

The following are a few remarks which have suggested themselves upon an inspection of these tabulated results:—

The specimens of iron prepared from the ores of the Northern District and from the Forest of Dean are remarkably free from phosphorus. This is readily explained by the very high quality of these ores, which are almost perfectly free from phosphoric acid. The considerable per-centage of silicon contained in a great number of the specimens of iron alluded to is perhaps less easy of

explanation. A reference to the composition of the specimen of Ulverston (Hæmatite) iron, given in the appendix to this Report, which was smelted with charcoal, and only contains 0.59 per cent. of silicon, would appear, however, to indicate definitely that the high proportions of silicon must be ascribed to the employment of hot-blast in the reduction of the iron at those works.

The products of the ores from South Staffordshire and South Wales which have been examined are, with two or three exceptions, of excellent chemical quality. Only three instances occur in these divisions of the series of iron samples (out of twenty-six samples from eight different works), in which the amount of silicon reaches two per cent. The samples from the Netherton and Old Hill Works (South Staffordshire) and the Blaenavon and Pontypool Works (South Wales), in the preparation of which cold-blast is specified as having been employed, the silicon, in only two instances (out of thirteen varieties of iron), slightly exceeds in amount 1.15 per cent.

The proportions of phosphorus and sulphur in irons from the ores of these districts are also inconsiderable in the majority of the samples examined. In the case of three only (out of twenty-six) does the amount of sulphur reach to 1.10th per cent., and the phosphorus amounts to less than 0.5 per cent. in twenty instances; of the other six, three contain less than 0.6 per cent.; one from the Old Hill Works contains 0.63 per cent., and two samples from Brierly Hill Works contain 0.63 and 0.72 per cent. The ores employed at the latter works contain somewhat high per-centages of phosphoric acid, the effects of which on the composition of the iron produced are, therefore, clearly traced. The per-centages of phosphoric acid in the ores used at the Old Hill Works (particularly in the "Balls," Bilston), are also higher than those in most of the ores used at the remaining South Staffordshire Works; and its influence on the quality of the product is, to some extent, shown by a reference to the composition of some of the irons from those works.

That the proportion of phosphorus in the iron is not always determined by the proportion of phosphoric acid existing in the ore employed need, however, be scarcely pointed out; the fact may be exemplified by reference to some of the samples of iron from the works last alluded to, and to the iron from the Lays Works, near Dudley, in which the per-centage of phosphorus is small, while the phosphoric acid in the ore is comparatively high. The circumstance that the proportion of phosphorus in all the samples of iron from the Blaenavon Works is small, while several of the ores employed contain considerable quantities of phosphoric acid, is probably to be ascribed to the employment of cold blast in the reduction of the iron at those works.

The Oolitic ores and the clay ironstones employed at the works in the North Midland and North Staffordshire districts, from which specimens were submitted, as also the ochrey brown ironstones employed at the Northamptonshire Works, contain proportions of phosphoric acid, which are more considerable than those existing in the greater number of the other ores examined. Thus, the ore employed at the South Bank Furnaces contains nearly two per cent. of phosphoric acid; that used at the Stockton Works contains upwards of 1.5 per cent., and very nearly the same amount exists in one of the ores at the Butterley Works, and in that employed at the Goldendale Works (North Staffordshire). The proportions of phosphorus in the various samples of iron from these sources exceed one per cent., excepting in one sample from the Butterley Works, in which, however, it amounts to 0.72 per cent.

The samples of iron produced from Northamptonshire ores also contain more than one per cent. of phosphorus, the proportions of phosphoric acid in the ores are, however, not quite as high as those last alluded to, amounting to 0.84 and 1.03 per cent. The samples of iron from one of the works

(the East End Iron Works) are, moreover, stated to have been produced with cold blast.

The North Staffordshire ore, used at the Goldendale Works, contains nearly 1.5 per cent. of phosphoric acid, and the proportion of phosphorus in the iron produced from it just exceeds one per cent.

A general inspection of the results obtained in the examination of the samples of ores and of the iron varieties produced from them appears to justify the following conclusions, upon which metallurgic chemists are now tolerably well agreed:—

1. The proportion of silicon in iron is much less influenced by the constitution or quality of the ores employed than by the conditions of smelting. A reference to the composition of the Northamptonshire ores and iron samples (particularly those from the Heyford Works), indicates that under certain circumstances, among which may probably be included a deficiency in alumina in the ore or the flux employed, an ore containing much silica is very liable to furnish a highly siliceous iron.

2. The proportion of sulphur existing even in light grey pig-iron is never so considerable as to exert an appreciable influence on the properties of the metal; and none of the descriptions of British ores which have been examined in connection with this report contain an amount of sulphur compound sufficient to exert any prejudicial influence on the quality of iron produced from them.

3. The proportion of phosphorus in iron is, in great measure, determined by the per-centage of phosphoric acid in the ore employed, while, at the same time, it is probably to some extent regulated by the temperature at which the reduction is effected (*i. e.*, by the employment of hot or cold blast).

The various ores examined, if classed according to the per-centage of phosphorus in the iron reduced from them, would stand in the following order:—

No. 1. Northern District and Forest of Dean ores, used by the Whitehaven, Weardale, and Parkend Works.

No. 2. South Staffordshire ores, used at the Netherton, Parkhead, Old Hill, Lays and Level Works.

South Wales ores, used at the Ystalyfera Works.

South Wales ores, smelted with cold blast at the Blaenavon and Pontypool Works.

No. 3. North Midland ores, used at the West Hallam Works.

No. 4. Northamptonshire ores, used at the East End and Heyford Works.

North Staffordshire ore, used at the Goldendale Works.

North Midland ores, used at the Butterley Works.

No. 5. Cleveland ores, used at the South Bank and Stockton Works.

It will scarcely be out of place to conclude these few remarks on the results of the analytical examinations, with some notice of the very considerable difference observed in the structure of many of the samples of iron analysed, and particularly in the physical condition of the so-called graphite, as exhibited by fresh fractures of the metal. In some instances a grey iron containing a per-centage of graphite similar to, or even higher than, that in a second example, exhibited a dense compact structure, while that of the other sample was open-grained, and showed the existence of the graphite in large and distinct scales. These modifications in the structure of pig-iron are so well known, that they are only alluded to because it is to them that must undoubtedly be ascribed, in many instances, the apparent discrepancies (which may be noticed by a comparison of the results included in this report) between the chemical quality of a sample of iron and the results which it has furnished when submitted to mechanical tests. It is self-evident that a sample of grey iron, compact and uniform in structure,

may resist the application, for example, of a much more considerable tensile strain, than one which is of higher chemical quality (*e. g.*, containing less silicon or phosphorus), but of which the structure is comparatively open and irregular. There is little doubt, also, from the results of numerous experiments which have been made in this direction, that the effect of adding considerably to the strength of some kinds of cast-iron, by repeatedly re-melting them, is, within certain limits, due to no important chemical change effected in the iron, but to the gradual production of a more thoroughly uniform mass, in which the graphite carbon has gradually undergone a material change in its state of aggregation.

CAPTAIN BLAKELY ON THE ARMSTRONG GUN.

THE following letter claiming a royalty on every Armstrong Gun that is made has been addressed to the Secretary of State for War by Captain Blakely, H.P. Royal Artillery:—

SIR,—The late Secretary of State for War having left undecided a case of great importance to me, and the correspondence on the subject being voluminous, I have the honour now to lay before you in a simple form the principal facts.

In 1854 I discovered a method of constructing cannon (or other tubes) whereby greater strength can be obtained from the same thickness of the same metal than by any other known method; in September I offered to the Duke of Newcastle to communicate my plan to any person his Grace wished, who was capable of understanding the subject, but was referred to the Ordnance Select Committee; in November I went, at considerable expense, to Constantinople and Belaclava, and tried in vain to persuade Lord Lyons to use my invention for some heavy guns to destroy the sea-forts of Sevastopol, and for some huge howitzers to shell that place from steamers at a distance of two or three miles. On my return to England in January, 1855, you may recollect, Sir, that you were good enough to give me a note of introduction to the Duke of Newcastle, who then immediately received me, and put me in communication with Colonel Lefroy on the subject. From this scientific officer, however, I learnt with much regret, that he personally could do nothing to recommend my plans or the reverse, but that they must be laid before the Ordnance Select Committee. Knowing the uselessness of approaching that body with a novel invention, the only proof of whose utility rested on mathematical calculations, I at once set to work to get a sample gun made. Having already been at expense in going to the East, and being about to enter on a course of costly experiments, I now took out a patent (dated the 27th February, 1855). Before attempting thus to ensure any profit to myself, you will perceive, Sir, that I had offered my invention to the country as a free gift, and given myself much trouble to press its acceptance on it. I was extremely fortunate in my choice of a manufacturer, and by the end of March the Butterley Company had completed for me an 18-pounder gun, which was tested near their works in Derbyshire, and whose strength exceeded my expectations. I applied to Lord Panmure for leave to have it tested at Woolwich by the Ordnance Select Committee, but as a communication between the War Office and the Committee, through the Lieutenant General of Artillery, required six or seven weeks, I had the gun altered for further private experiments. It was an excellent 18-pounder gun, fully equal to the service gun, though little more than one-third its weight: I had the bore enlarged to the size of a 24-pounder, reducing the thickness of metal where the greatest strength is requisite to 2½ inches. As the thickness of an ordinary 24-pounder is there 6½ inches, I can have had no expectation that mine would be equally strong; I only wished to see how strong it was. Having by the middle of May obtained permission to send the gun to Woolwich, I did so, and explained to

* The Committee of 1854 was differently constituted from the present one.

the Committee how I had altered and weakened it. It was tried, and after being fired several rounds with 4 lbs., 5 lbs. and 6 lbs. of powder, a solid 24-pounder shot, and two wads, it absolutely twice bore a charge of 8 lbs. of powder and the shot and wads, bursting at the third round. To my astonishment, the Committee reported that "guns so constructed could never be considered safe."

Some scientific members having been added to the Committee by the Duke of Newcastle, and having been invited by the President to sit (in consequence of representations, which have secured me the hostility of the Committee ever since), I early in June presented the calculations on which I formed my theory, and obtained leave to send another gun for trial. The calculations were reported on by a mathematician, Mr. Heather, and declared inapplicable to cannon. The gun, however, a 9-pounder, was most completely successful. A cast-iron service gun and a brass service gun of the same calibre were fired round for round with it, with the same charge of powder, so long as they stood. All three were fired:—

2 rounds with 8 lbs. of powder, 2 shots and 1 wad.					
86 "	3 lbs.	"	1	"	1 "
26 "	4 lbs.	"	1	"	1 "
5 "	5 lbs.	"	1	"	1 "
5 "	5 lbs.	"	2	"	1 "
110 "	6 lbs.	"	2	"	1 "

Here the cast-iron service gun burst. The other two were then fired:—

74 rounds with 6 lbs of powder, 2 shots and 1 wad. Here the brass gun became unserviceable from loss of shape, mine alone remaining, and being fired afterwards:—

13½ rounds with 6 lbs. of powder, 2 shots and 1 wad.

So great was the endurance of this gun, that the experiment lasted nineteen months, consequently was not officially reported till 1857. A 69-pounder was then ordered to be made at the Government foundry at Woolwich, further to test my plan. The gun has been made, but, I believe, has not been fired to this day!! Meanwhile I have made many private experiments.

In 1855, Mr. Robert Mallet, assisted by an eminent mathematician, Dr. Andrew Hart, of Trinity College, Dublin, planned the construction of cannon on the same principle I advocate. He obtained the sanction of Lord Palmerston to expend a large sum of public money to test the truth of the theory; the Ordnance Select Committee having reported it unsound. I could bring forward, if necessary, many more proofs that the value of this method of manufacture was unknown at the commencement of the year 1855, at least to the British Government and all their official advisers; but those I have here stated will, I trust, Sir, remove all doubt on that subject from your mind: the Ordnance Select Committee reported that "guns so constructed could never be considered safe," and even after witnessing the wonderful endurance of two guns, desired to see further experiments. They cannot pretend to have known the value of the method before! Nor can Lord Palmerston's Government, as that statesman sanctioned Mr. Mallet's spending thousands to test it.* Nor can any of those who have sanctioned the manufacture of 3,000 or 4,000 guns within the last three years on the old plan.

This being the case, and I have spent upwards of £1,500 in experiments and in urging the Government to use my method, I have no hesitation in asking you, Sir, now that it is adopted, to cause to be paid to me a suitable royalty on each gun manufactured according to my patent either in the Royal Arsenal at Woolwich, or by private

* I published, in the *MECHANICS' MAGAZINE*, my reasons for believing Mr. Mallet's mortars would fail, before they were tried. He had underrated the strength required.

contractors for the use of the Government, or else to purchase my patent. The cannon on which I claim a royalty are now known as Armstrong guns, but their strength is obtained by the plan I advocate, as you will at once perceive, Sir, by comparing the published accounts of each.

Provisional Specification left by W. G. Armstrong at the Office of the Commissioners of Patents, with his Petition, on the 11th Feb., 1857.

"I, WILLIAM GEORGE ARMSTRONG, of Newcastle-upon-Tyne, in the County of Northumberland, Civil Engineer, do hereby declare the nature of the said Invention for 'Improvements in Ordnance,' to be as follows:—

"The improvements relate, firstly, to forming guns with the internal tube or cylinder of wrought iron or gun metal in one piece, surrounded by one or more cylindrical castings of wrought iron or gun metal shrunk upon the internal cylinder," &c.

In the *MECHANICS' MAGAZINE*, of Feb. 25th, it is said that the Armstrong gun

"Is formed of an internal steel tube, bound over with strips of rolled iron laid on spirally."

(Here other extracts from Captain Younghusband's paper* the *Times*, the *Daily News*, and other journals follow.)

Of these extracts I would wish, Sir, to draw your especial attention to that from Captain Younghusband's report,—"*the parts are then in that state of initial tension which is necessary;*" and to that from my own description,—"*by forcing on the rings the necessary degree of tension can be obtained;*" because this tension is the essential and novel feature; and the similarity of expression is striking. If the necessity for this tension was known before to any one, and cannon were publicly constructed accordingly, my case is not good (though even could that be proved I fancy I have some claim on Government, having spent a large sum of money to prove this necessity to them, *they denying it*), as the words of Her Majesty's patent to me declare it void "if the said invention is not a new invention as to the *Public Use and Exercise* thereof in our United Kingdom of Great Britain and Ireland, the Channel Islands, and the Isle of Man." Sir W. Armstrong's own letter is, I presume, conclusive, that his first cannon was made on my patented plan; "the gun," he says, "is composed internally of steel, and externally of wrought iron, applied in a twisted or spiral form." I am informed that now he makes the inside of wrought iron, thinking thereby to evade the words of my patent, while retaining the only essential feature of it, viz: the tension on the outer part. This might do for a private individual, but I feel certain Her Majesty's Government, so long as you, Sir, are Secretary of State for War, will never sanction such an evasion. Even were it fair, or even legal, it would be most prejudicial to Her Majesty's service to substitute an inferior metal for the inside of the gun, merely to save the trifling

royalty due to me. That wrought iron is inferior is acknowledged by Sir W. Armstrong himself. He tried it, Captain Younghusband says, and abandoned it for steel. That he did not afterwards abandon steel, because it failed, is proved by his concluding words when writing to the *Times* about his first gun, which was made with a steel core:—

"It now only remains to be stated, that 'in course of the long series of experiments made with this gun it has been fired nearly 1,300 times without sustaining any permanent injury either in the breech-loading arrangement or otherwise. The only parts exposed to wear (and none are seriously so) are separable from the gun, and can with great facility be renewed.'"

On this point Captain Younghusband's evidence is still more decisive. After describing numerous experiments made at Shoeburyness with the gun, he tells us that—

"Mr. Armstrong, believing the gun to be stronger than necessary, suggested its being returned to him to have it re-bored for a heavier projectile."

Why then did Mr. Armstrong in the later guns use wrought iron? Evidently to attempt to evade my patent. On the publication of his letter in the *Times* of January 3rd, 1857, I sent it and my specification to a lawyer, and asked him if my patent included the method described in the letter. His reply was that it did, and that, without my permission, Sir William could not continue to manufacture his guns. I wrote to inform Sir W. Armstrong, and obtained a reply promising to "negotiate" with me before "using" the invention "commercially." This promise was written on the 21st of January, 1857, yet on the 11th of February, three weeks later only, Sir William filed a provisional specification substituting wrought iron for the steel and cast iron mentioned in my patent! In November, 1856, I had the pleasure of seeing Sir Wm. Armstrong at his Engine Works, near Newcastle. On that occasion he expressed views exactly coinciding with my own, published nearly two years before, and distinctly told me that the *principle* of the construction of his cannon was to have the exterior in a state of permanent strain, and that it mattered little which of several suitable metals were used. He then agreed to manufacture a gun for me on my plans in which the above-named principle was to be applied by forcing a small tube into a cast iron larger one, the latter forming nearly the entire gun. He afterwards declined making it.

I am advised by eminent lawyers that neither this nor any other unimportant alteration would enable him legally to use the essential feature of my patent. I was prepared to try the question this summer by an action against the Elswick Company, but was stopped by a declaration by General Peel that if I continued it, he would cease to consider the question of the infringement of my patent rights in Woolwich Arsenal, or at least to correspond with me on the subject.

In choosing whether I would submit my case to the decision of a legal tribunal, where any quibble might have deprived me of my rights, or to that of an English statesman and gentleman, I could not hesitate. I made a discovery of great value to my country; I offered it to the country, and urged its acceptance; to enable me to raise money to prove its value, which after being denied for four years has now been acknowledged, and my plans adopted, not only as better than the old system, but as the only known method whereby sufficient strength can be obtained for rifle cannon of any size. This has been proved by the bursting of the 32-pounder and 69-pounder guns rifled by Mr. Whitworth, and by that gentleman immediately adopting my plan for those guns he is now making.

It remains for you, Sir, to decide what the country shall do for me; I can thank my God that He has enabled me to do my duty to it.

I have the honour to, Sir,
Your obedient servant,
A. T. BLAKELY.

The Right Honourable The Secretary of State for War, &c., &c., &c.

THE NEW BRONZE COINAGE.

A CORRESPONDENT of the *Times* writes as follows:—A very sensible article, extracted from the *MECHANICS' MAGAZINE*, has been inserted in several of the daily papers on the above highly important subject, and I respectfully beg a small space in your columns, while I, as a practical engraver of some experience, endeavour to answer it. I shall feel too glad that if by your kind insertion of the opinion of one of the profession it should succeed in inciting others with more ability to supply my defects in striving to vindicate the national ability of the engravers, designers, and modellers of the present age. I will first glance at the highly commendable and honourable desire for improvement that has lately been shown in all our late national undertakings in connection with the fine arts, viz., by means of a public and general competition, judging the relative merits and capabilities alike of the highest and lowest engaged in the work required, and I ask you, Sir, the editor of the leading public journal, and the public generally, if it has not been of the greatest advantage to the country; therefore, why should not the same course be followed in the present instance? I have such perfect faith in the versatility of genius of our native artists that I have no hesitation whatever in saying they will relieve our Lady Emblem from the uncomfortable position she has occupied for so many years. The questions raised are:—

What impressions are to be given to the new bronze coins, and why not have something new? To this I answer there is indeed a vast field open for improvement.

Again, is there so much poverty of inventive skill among engravers that there is danger of getting something worse than the present impression?

I here assert that if the means of publicly and generally testing the question be allowed, there will be found plenty of native artists capable of making and executing a better design. To the last question, is there no one in the kingdom who has talent enough to sketch out a design which would at once be symbolical of the ocean's sovereignty of Great Britain, and a fit impression for its coinage? I finally reply, let the opportunity be given of trying the fact, and proof would be shown that our countrymen have not degenerated, but will be found in numbers, ready, willing, and competent to execute a design that shall at once be a fit emblem to represent the coinage of the first country in the universe as it will the artistic skill of its people. Let me entreat, Sir, your powerful and generous advocacy in aid of the following proposition, should no better be found:—

1. That there be a public competitive exhibition of pencil or sepia drawings and wax or plaster models, about six inches in diameter.
2. That the exhibition be holden within this present month.
3. That artists of every grade be invited to compete.
4. That the judges appointed shall choose a design from the drawings or models exhibited, and if their choice of design should not be the work of a practical engraver or artist, capable of carrying out the design, let a given sum be paid to him for the drawing or model chosen, and then give the commission to the best practical exhibitor for execution.
5. That the judges appointed be unconnected in any way with any of the exhibitors.

It is reported in Toulon that orders have been received from the French Admiralty to cease disarming the fleet, and that the forts commanding the entrance to the harbour are being armed with the guns which have hitherto been kept in store.

One of the Armstrong guns, an 80-pounder, forged at the Elswick factory, was recently tested in the long range at Shoeburyness, in the presence of the Ordnance Select Committee at Woolwich Arsenal, and gave the most wonderful results as regards accuracy, &c. The flight obtained was 9,000 yards, or upwards of five miles.

ELONGATED POINTED RIFLE SHOT FOR VERTICAL FIRE.

"TO THE EDITORS OF THE MECHANICS' MAGAZINE."

GENTLEMEN,—In your Magazine of last Friday you were so kind as to give a drawing with a description of my elongated flat-faced iron or steel rifle bolt. I shall now be much obliged if you will be so good as to insert a drawing of my elongated pointed rifle shot. The four-grooved wooden jacket is cut out of a piece of seasoned willow wood, with a sharp rifle cutter corresponding with the bore of the rifle; a hole is drilled out the centre of the jacket, which is then placed in the rifle mould, and the molten lead is poured through the hole, thus forming the body of the shot and a leaden disk protecting the base of the wooden jacket. In the year 1851, when the Kaffir war was raging, and the letters of many officers from the scene of action stated that the Kaffirs sheltered themselves in the, to the British soldier, impenetrable jungle of thorny mimosa, in the midst of stony and rocky ground, where our horizontal fire of musketry could make no impression on them, I wrote to the editor of the *Naval and Military Gazette* suggesting that my elongated rifle-shot and percussed shells fired vertically might have the effect of driving the Kaffirs from their jungle strongholds. The editor inserted my letter, but with an observation of his own, that Carnot made experiments by firing vertically round bullets from mortars, howitzers, and carronades, but that in their fall they made but a slight impression on boards placed on the ground. Now, the nature of Carnot's round shot vertical experiments bore no analogy to my plan of firing vertically elongated rifle shot and percussion shells. My plan resembled the arrow shower, Carnot's that of a ball falling from a sling. Every archer knows how deeply an arrow falling vertically penetrates the ground, and that it requires some force to draw it out.

I am, yours obediently,

J. NORTON.

Rosherville, 5th September.

THE "NAVIES OF THE WORLD."

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—I have not the slightest wish to enter into any dispute, nor to prolong this correspondence further than may be requisite for the statement of the following facts:—

1. With regard to the articles in the "Conversations Lexicon," which you say "was not printed in the *Times*, nor heard of in England until January"—this article originally appeared, I believe, last September, and had, as I observed, "made a great sensation throughout Europe" long before it was discussed in England. The translation of it given by me in the "Navies of the World," together with the greater portion of the critique thereon, was in type last November.

2. The list of the French navy was in type shortly after, as was also a large portion of the rest of the book, though it was not published in its present form till the 28th May.

3. The parliamentary papers you allude to I did not see till March. The information extracted from them, which is not furnished in the appendix, together with the comments upon Sir John Pakington's and the extracts from Sir Wm. Armstrong's speeches, together with various other subjects, were embodied with the matter already in type (and which had, of course, been "kept standing") just before the volume went to press.

4. The work you name, Mr. Isherwood's "Engineering Precedents for Steam Machinery," I do not remember ever to have heard of, nor did I ever see the quotations therefrom in your Magazine of the 18th February. There can, therefore, be no extracts from that book, nor from your

columns, in my fifth chapter, the greater part of which, if I recollect rightly, was written a twelve-month ago. I remain, Gentlemen,

Your obedient servant,

THE AUTHOR OF THE "NAVIES OF THE WORLD."
Bridgenorth, 5th Sept., 1859.

[The above letter calls for but very few remarks from us, since it offers no contradiction whatever to our comments of last week. We can assent to all four of Mr. Busk's "facts," and still leave the subject precisely as we then stated it. We regret, however, for Mr. Busk's sake, that he has not the candour to acknowledge plainly that our first estimate of the book was fairly formed. Seeing evidences of very recent composition in all the chapters, and finding them plentiful in many places, we concluded that the book was recently written, and every intelligent reader of it will do the same. From this conviction, we are quite content to let Mr. Busk's explanations have whatever weight may belong to them, notwithstanding the difficulty we ourselves have in accepting some of them. Take this 4th "fact" of the above letter, for example. Mr. Busk says he has never read either Mr. Isherwood's work or our quotations from it. How difficult it must be for us to believe this statement the reader will judge when we put two passages side by side, thus:—

Mr. Isherwood, as quoted in the *MECHANICS' MAGAZINE* for Feb. 18, 1859.

Mr. Busk's "Navies of the World," p. 146.

"The machinery of the gun-boats, though well made, and by the best builders, was constantly out of order. Both boilers and engines gave continual trouble; the first from the use of high pressure steam and water; the last from the high rotary velocity employed. In fact, the rotary speed of the engines was so great that it was impossible to keep them in order. During the hostilities at and around Canton, the English established a shop on shore at Hongkong for repairing; they also had, at the same place, the floating workshop, "Volcano," sent out from England, completely fitted up with tools and power for doing a large amount of casting, forging, and finishing; and both these establishments were kept constantly employed on the gun-boats, there being, out of about fifteen, usually a couple undergoing repair; in fact, the repairs upon them were enormous. For economy of fuel, durability and reliability as war vessels for constant use, the machinery of these gun-boats cannot be recommended, however well adapted to the momentary purpose for which they were constructed."

"Well made, however, as the machinery of these gun-boats was, and by the best makers, both engines and boilers are constantly getting out of order, owing no doubt, in a great measure, to the excessive velocity of the screw. The fifteen gun-boats employed in the late Chinese war constantly kept two large steam factories (one afloat and one ashore) at work in executing their repairs; therefore, until some more durable machinery can be devised, these vessels can hardly be considered available, except for temporary emergencies in hostile operations upon an enemy's coast."

Now, we ask any man of the slightest experience in literary matters to read the above extracts carefully, and then tell us if he finds it easy to believe that the writer of the second extract had never read the first, particularly when he remembers that Mr. Isherwood (as we said in February) "derived most of his information respecting our gun-boats from personal examination of those employed in the capture of Canton," he being in China at the time. But we do not wish to urge such objections further. Let those who have confidence in us do the best they can with Mr. Busk's statement; as for others, they may read the book for themselves, and then judge us harshly—if they can. EDS. M. M.]

THOMAS'S HEAVY RIFLED CANNON FOR GUN-BOATS.

THOMAS'S HEAVY RIFLED CANNON FOR GUNBOATS.

THE author of the interesting paper on "Experiments in Gunnery" given in this number, in the volume from which that is taken proposes the use of the powerful rifled gun represented in side and front view in the annexed engraving. He says our own heavy guns are constructed upon a principle so false that the only wonder is that so few accidents happen with them; those of the largest size are not only unsafe, but also very inferior in power to the American guns. If, however, it should be discovered that rifled guns of six or eight tons weight—the weight of some of the guns employed in the American service—can be constructed of wrought iron, then, indeed, a powerful piece of ordnance will be obtained; a compound shell, of 2 cwt. and upwards, could be fired from it, and a greater range and accuracy combined would probably be attainable, than could be acquired with any other description of gun, such as could with convenience be used. A fortress or a floating battery, attacked with ordnance of this kind, could scarcely escape destruction. The length of the bore of the gun here illustrated is nine feet, and the calibre eight inches; the metal which surrounds the charge is nearly twelve inches in thickness; this (if the guns were constructed of the new puddled steel) would probably be sufficient to give it ample strength, and weight enough to prevent great recoil. A shell of 2 cwt., similar to that shown standing on end below the muzzle of the gun in the engraving, and a charge of from 25 lbs. to 30 lbs. of powder, might be used with it; *a* is the front view of the gun. "A long, low, strongly built vessel, possessing great steam power, armed with a gun of this kind, would prove," says Mr. Thomas, "infinitely more destructive than the steam battering-ram which has recently excited some attention. A vessel such as I have described would possess great advantage over a steam-ram, from the difficulty which would be experienced with the latter—first, in striking a vessel under sail or steaming; and secondly, in getting disengaged from it afterwards.

"Ten or twelve vessels of the above description—sea-going gun-boats—each armed with a heavy rifled gun to throw shells of 2 cwt., and with steam power sufficient to give them a speed of at least fourteen knots, would, at a distance of three

miles,* lay any town on the coast in ashes, in a very short time, and with perfect impunity. This may be accomplished, and *will* be; if not by our own nation, by another. It is questionable, however, whether the 11 or 12 inch guns, such as form the armament of the American corvette, Niagara, would not prove more destructive in close action—from their large diameter and heavy bursting charges—than even the powerful rifled guns which I have described. Before adopting rifled guns into our naval service, to the entire exclusion of smooth-bored guns of large calibre, much consideration would be necessary, and many experiments required to be made. I see no reason, however, against the acquisition of such a gun as I have described. The only difficulties which lie in the way of it have already been once surmounted in the case of Messrs. Horsfall's 13-inch gun, and will, no doubt, be still more completely overcome. The great tensile strength which is required for guns to throw compound shells arises from the absence of windage, and also from the friction on the whole surface of the bore, which impedes the progress of the shell along the bore, and allows the fluid produced by the fired charge to accumulate behind the shell, and thus to exert a great strain on the gun. Nearly the maximum results as to range and general effect—regarding the means employed—might be attained with the gun represented in Plate 7. Any larger piece of ordnance would not only be unmanageable, but probably unsafe; and although a larger gun could, of course, throw a heavier projectile, still a comparatively greater effect could not be obtained with it, as the range of the larger shell would probably not be greater, unless a higher velocity could be given to it; so that, to acquire the same relative effect, comparatively greater means would have to be employed.

* At this range such a gun would not require an elevation of more than about 11°.

ON EXPERIMENTS IN GUNNERY.

By LYNALL THOMAS Esq., F.R.S.L.

GUNNERY furnishes no exception to the rule, that there must be a cause for every effect; indeed, in scarcely any investigation is a knowledge of causes more essential than in conducting experiments in gunnery. Hence, when we find that two shots, fired apparently under precisely the same circumstances, show a variation in their range, or in their accuracy, we know that a cause must exist why this should be the case; and although the fact of the variation in the effect of shot fired under similar circumstances shows that general rules only are applicable in gunnery, and that no single result is to be relied on, yet a proper study of cause and effect in this matter will considerably reduce the chances of failure.*

It is not sufficient merely to obtain a greater range, accuracy, or general effect; but we should know, also, how these results are obtained, if we wish to profit by them in the greatest possible degree.

Before any new principle can be successfully applied in practice, repeated failures must always be expected. I may go so far as to assert that they are absolutely necessary to the complete attainment of success. Because the Lancaster, Whitworth, and other guns may have failed in fulfilling the expectations that were formed respecting them, their trial is, by no means on this account, to be considered as an entirely useless expenditure of either time or money. On the contrary, it was necessary that they should be made, and, no doubt, considerable advantage in many respects will arise from their having been made.

When men possessing mechanical skill in the highest degree—as Mr. Whitworth for instance—undertake experiments with a view to any improvement in the construction of implements, whether of a warlike or a peaceful character, good must always result; for, even if they fail in establishing their views, considerable light will always be thrown upon the subject to serve as a guide for the future. Still, although the aid of able mechanicians is of great importance in the

* These somewhat trite remarks were called forth by an observation which was made to the author by an artillery officer of some eminence—to the effect that "the firing of the charge with cannon was attended with such varying results, that it was useless to think of applying any rule for regulating the thickness, or strength of metal, required for guns of different calibres."

practical application of the theory of rifled cannon and projectiles, the theory itself is, nevertheless, a philosophical rather than a mechanical question.

It will require systematic and well-conducted experiments, extending over a course of many years, before a sufficient knowledge can be acquired of all the circumstances attending the application of the principle of the rifle to cannon, to enable us to decide upon the best practical system for the construction either of the gun or the projectile. The different methods of applying the principle of the rifle to cannon—as, by having the gun to load at the breech, or the muzzle; or, having a compound, or a homogeneous projectile, will each have to be the subject of numerous experiments.

It is all the more imperative that these experiments should be undertaken by the Government, inasmuch as no person—so small is the knowledge which has as yet been generally acquired of this subject—is at present really competent to give an opinion upon anything new in connection with it which may be brought before their notice. I think I should not be far wrong in asserting that only a very few persons connected with the War Department are yet fully aware either of the comprehensive nature of the subject of rifled cannon, or of their want of knowledge in everything relating to it. To stand by and witness the trial, at Woolwich or Shoeburyness, of a number of projectiles, or a new gun—the result, in general, of private experiment—teaches little or nothing. Much more is learned by firing a single shot—made expressly for the purpose of ascertaining some particular effect—and by a thorough examination and careful study of all the circumstances attending its projection, than by merely witnessing the firing of twenty thousand projectiles devised by other persons. The results obtained with the latter may be apparent enough, but the train of reasoning (the fruit of personal experience) which produces these results, remains altogether unknown; for although a man may communicate the result of his experiments, yet he cannot furnish another with his personal experience; and without this it is perfectly impossible to effect, or even to suggest, any important improvement.*

There is scarcely a question—if, indeed, there be one—in the whole subject of dynamics, or the laws which relate to a body in motion, which is not involved in the investigation of the circumstances attending the flight of elongated projectiles; these require to be thoroughly investigated and known before any decided opinion can be given as to the best practical method for constructing rifled cannon. A system founded upon mere guess-work would have a very unsound basis.

It has been too much the custom to speak slightly of theory in gunnery. This is probably owing to the unsatisfactory state of the ordinary theory of gunnery; but the acquisition, in this instance, of a sound theory is of the highest importance. The stride which has been made in the practice of gunnery since Robins's experiments were made known, resulted from his discoveries respecting the laws which govern the flight of projectiles, and respecting the nature of the projecting force. When once a theory had been framed, based upon sound principles, the mechanical improvements followed as a matter of course.

Sufficient attention has not hitherto been paid to the correctness of the principles upon which the cannon and projectile should be constructed. To this chiefly must be attributed the failure of the Lancaster and Whitworth guns—the projectile in the former case acting like a wedge; in the latter like a lever in the bore of the gun.

* The truth of this remark is exemplified in a striking manner by the fact that the rifled cannon and projectiles produced at Woolwich by artillery officers, who had before them the results of all the experiments made from time to time at Shoeburyness, proved most signal failures. This fact also affords a proof of the defective nature of the ordinary theory of gunnery, and of its small utility in estimating the comparative results to be produced with long projectiles.

To produce any great and useful results, a combination of sound theoretical and practical knowledge is necessary, and this can only be obtained by a long and close study of the subject, and by numerous experiments carried on with unremitting attention.

No single invention—as of a projectile—a method of loading at the breech—a peculiar form of groove, or any other mechanical contrivance—is of the least use in itself, unless a perfect combination—such as the proper length of the gun—of the turn—the most suitable metal for the gun, &c.—is obtained for rendering it effective. If each of these be not adapted to the others, the whole must inevitably fail in practice. It is the difficulty of effecting this combination which renders experiments with rifled guns so complicated and costly. If properly conducted experiments had been at first undertaken by the Government at their own expense, instead of relying upon the inventive and pecuniary resources of private individuals for the acquisition of their data—which, to say the least, is a rather pitiful course to adopt; for, if a new thing is worth trying, it must surely be worth the cost of the trial—the public would have been spared the expense (amounting to between three and four hundred thousand pounds) of the Lancaster gun factory.

Notwithstanding, therefore, the numerous experiments which have been made in gunnery, and the immense mass of data which must have resulted from them; yet, owing to the desultory manner in which the experiments have been carried on, they have been productive of much fewer practical results than we might reasonably have expected. Experiments with rifled cannon not only require to be conducted systematically; but, to be productive of real benefit, they also require to be conducted by properly qualified persons.

The questions which constantly arise in gunnery experiments are sometimes so complicated and difficult of solution, that none but a mathematician of the highest order can really ascertain the value of the results which are obtained. To conduct experiments in gunnery, therefore, in a proper manner, it is of the first importance to have a good mathematician to collect and arrange the data, and to ascertain the exact numerical value of the results obtained.

It will be also necessary to have a practised experimentalist to profit by these results; one who, with a proper knowledge of cause and effect, is capable of suggesting the best method for the attainment of certain objects. A clever mechanic, to invent and judge of the means which can best be employed for carrying out the plans suggested, should also assist in conducting such experiments, to ensure their being attended with the most useful results.*

The whole of these qualifications are rarely combined in a single individual. Robins was a remarkable exception, and his experiments, in consequence, formed an era in gunnery.

But although the necessary qualities are seldom found in one person, there is no reason why several persons should not be selected, who would, collectively, possess them; and who might either be placed on the Rifled Ordnance Committee, or act with it in such a manner that their services would always be at its disposal, or at that of the presiding officer at Shoeburyness (an important office, for which no one could be better qualified than the gentleman who now fills it); the results of their operations to be finally submitted to a committee of experienced military men of all services, who would be able to judge of their practical value.

A systematic course of experiments conducted under such joint superintendence would be the right course to take for acquiring the proper data respecting all the circumstances connected with

* The appointment (since this was written) of Sir W. Armstrong, as Engineer to the Rifled Ordnance Committee, will no doubt prove highly beneficial; in that he appears to possess the last-named qualifications in a very eminent degree.

rifled ordnance, in a much shorter time and more satisfactorily than could otherwise be the case. To conduct experiments in a desultory manner is invariably a useless expenditure of both time and money.

It is impossible for a private individual to undertake such experiments on a sufficiently large scale to be productive of conclusive results; they should be conducted somewhat after the manner of Hutton's experiments, only on a much larger scale, each with a view to some well-defined object. The following are amongst the chief circumstances in connection with rifled ordnance, respecting which some certain data are required, and each should therefore be the subject of a separate course of experiments.

1. Experiments with the ballistic pendulum for finding the different velocities of rifle shot under various circumstances; so that both the initial velocities given by different charges of powder, and the loss of velocity—occasioned by the resistance of the air—which the shot suffers in passing through different spaces, shall be thoroughly ascertained. At present literally nothing (certain) is known with respect to these points.

These experiments in the case of rifled shot ought to be attended with better than ordinary results, as the pendulum could be placed at a greater distance than usual, on account of the superior accuracy of flight of rifled shot.

2. The different quantities of friction in the case of both compound and iron shot of different kinds; and the loss of range occasioned by it.

3. The effect produced upon the flight of long shot by any alteration in the position of the centre of gravity.

4. The effect produced by a difference in the form of projectiles.*

5. The difference in the ranges and deflection produced by different elevations with shot of different lengths.

6. The circumstances attending the penetration of long projectiles into various substances.

7. The angular velocity required for shot of different sizes, forms, and density, when fired with different velocities and elevations.

8. The form of groove, (both for iron and compound projectiles,) which shall produce the necessary effect with the least amount of friction.

9. The strength of metal required in the gun, whether it be destined for the employment of iron or of compound projectiles.

10. The curves, and also the times of flight, of long projectiles; in order to ascertain the best method for securing the greatest amount of efficiency in firing them at high elevations.

11. The effect of windage, especially with iron projectiles.

12. The effect produced by altering the length of the bore of the gun.

Besides those which I have enumerated, there are many other points relative to which sufficient data must be fully acquired before unerring results can be obtained. Those who, like myself, have made many experiments on a smaller scale, have acquired sufficient data, perhaps, to form by comparison a general opinion upon all these questions, and (assisted by some acquaintances with the ordinary theory and practice of gunnery) may even have arrived at the power of estimating their effects with a certain degree of accuracy; but the velocities of rifled shot when fired with different charges, the friction, and many other points, can only be ascertained by a regular course of experiments with the ballistic and gun pendulums, and by other means of much too extensive a nature for a private person to undertake.

Whilst the necessary experiments are being carried on, there is no reason why the country should be deprived of the use of rifled cannon.

* It would be a great advantage if the establishment at Shoeburyness were furnished with the means—at least on a small scale—of casting, forging, or altering experimental projectiles, so that they might be tried without delay. It would be a great saving in time, and, eventually, in expense.

The manufacture of the Armstrong gun may be proceeded with; but we need not confine ourselves exclusively to guns of this particular description. There are several methods by which a supply of very efficient rifled cannon may be obtained without going to an exorbitant outlay in the exclusive adoption of cannon of the most expensive kind, previously to a thorough trial of their merits in actual service, or before the utmost simplicity in their construction is attained. Enough has been said to show that the knowledge which has already been obtained bears but a small proportion to that which remains to be acquired, and that further experiments are therefore necessary.

The accuracy attained with the Armstrong gun is a beautiful mechanical feat, but one which will be commonly performed (and by much simpler means) when a better knowledge of the subject has been acquired; it has shown what can be effected with this particular combination, but little else has been learned from it; and until the truth concerning all the points which I have enumerated, and many others, be clearly ascertained, it will be impossible to decide as to which is positively the best system for the construction of rifled cannon.

To give an example of the change in opinion which experiment will effect, it is a remarkable fact that almost all the circumstances which the Ordnance Select Committee objected to three or four years since, as perfectly inadmissible in the practical adaption of the principle of the rifle to cannon—such as a compound projectile—a projectile composed of many pieces—a breech-loading gun—a gun constructed of wrought iron, especially in such a manner as not to be homogeneous—are united in the Armstrong gun.

In like manner, it will probably happen, when further experiments are made, that the description of rifled gun which will be finally adopted will differ as much from the experimental (for the whole are but experimental) guns which have been tried up to the present period, as these differ from the earlier attempts which were made; for as yet experiment has been directed almost solely to improvement in the mechanical application of a principle of which really very little (certain) is known; instead of being directed to the acquirement of a knowledge of what relates to the principle itself.

This it is which gives rise to such expensive blunders as the Lancaster gun factory; a greater blunder, however, will be committed if we adopt breech-loading guns to the exclusion of all others.* Fortunately, there is to be found amongst the members of each branch of our service a fund of sound common sense, which (and this, upon investigation, will be found, I believe, correct) always leads, eventually, to the adoption of the best thing of its kind, when its superiority has been properly established; although, in most cases, it is effected by a very roundabout and expensive process.

By neglecting, therefore, in this instance, to make proper experiments, we throw away advantages which would enable us to acquire the superiority with regard to projectile effect, the possession of which (especially in a country like our own, the confines of which are all coast) should be a matter of primary importance.

ASSOCIATION OF FOREMEN ENGINEERS.

THIS Association held their usual monthly meeting at their assembly rooms, 35 St. Swithin's-lane, City, on Saturday, the 3rd instant. Mr. C. F. Hayes read on the occasion a paper on the Manufacture of Rifles. He described with great minuteness many of the processes connected with the completion of these extraordinary *armes de précision*, as carried on at Enfield, and by contractors in various parts of England, Belgium, and America. A large attendance of members, considerable applause, and a unanimous

* The advantage of the breech-loading system, in allowing the men who serve the gun to be less exposed, is not so prominent with long-range guns as with others; since the former would more frequently be out of the range of musketry.

vote of thanks rewarded Mr. Hayes for imparting some valuable information on an interesting subject.

Prior to the reading of the paper it may be stated that several honorary members were elected and others proposed. The anniversary dinner of the Society, postponed many months by reason of the death of the late Chairman, Mr. Sheaves, too, was announced to take place at the above-named place on Saturday, 17th instant, at 6.30 p.m.

Mr. Newton presided.

Our Weekly Gossip.

THE following note has been addressed to the *Times* and *Notes and Queries*:—"In the *Times* of yesterday I observe that as soon as the breaking up of the Tartar frigate is completed in Chatham Dockyard, 'the St. Lawrence, one of the 46-gun frigates, will be taken into the same dock and broken up.' The St. Lawrence is, I believe, no other than that famous old Shannon which fought and captured the Chesapeake in the American war. Her name, having taken an imperishable place in history, was transferred some few years since to the large screw frigate which now bears it, and the renowned old hull has since been lost sight of under the name of the 'St. Lawrence.' If I am not mistaken respecting these facts—and I can hardly be—many will doubtless be glad to learn that a last look may yet be taken of this famous old vessel.—R."

A curious experiment is now being tried at Lyons for laying the dust in public promenades, and has so far been attended with success. A chemist of that city having accidentally spilt some hydrochloric acid on a terrace of his found that it hardened the spot on which it had fallen, and maintained it in a state of permanent moisture. This led him to think that by watering the streets with this acid the dust on large macadamised roads might be laid, or rather prevented from rising. Experiments were first made on the Cours Napoleon between the Rhone and the Perrache station. The success was complete, and has also proved durable, the carriage-way having now been several months free from dust; and another experiment is now being made on the Place Bellecour. During the hottest part of the day the ground, although dry and gravelly, has the appearance of being as consistent and damp as if it had been watered half an hour before. But as evening approaches the moisture becomes more and more perceptible. Every morning the ground is stiffer and more comfortable to walk on. This may easily be accounted for; the acid, decomposing the gravel or stone, forms one or several deliquescent salts, which, therefore, attract the moisture of the air. The question as to whether roads thus watered are likely to last as long as they ought, can only be decided by time.

The following paragraph appeared a week ago in the morning papers:—"The Trinity steam yacht *Argus* arrived at Harwich from London at about half-past 9 p.m. on Saturday, and had on board an experimental model of Maillard's patent mechanical compass for steering ships without needles or magnets. The instrument was merely lashed in the rudest manner to the after part of the paddle-box, and, notwithstanding the great disturbing force thrown and acting on the steering shaft of the instrument, which is immersed in the water, it worked and gave the ship's course with sufficient accuracy to establish the entire success of the principle on which the compass is constructed, and to justify the inventor's guaranteeing the perfect efficiency of his invention. These instruments are meant to be used in the stern of the vessel, and to stand on deck, where the ordinary compass stands at present; but the inventor selected the position in which his compass was placed on board the *Argus*, in order to put it to the severest test, and to see it in operation under every imaginable disadvantage. This compass can be used on land, and bids fair to supersede the magnetised needle wherever true bearings are required." We are rather curious to know, and to make known, more of Mr. Maillard's extraordinary compass. His application for the patent has, however, been made so recently that we fear we shall not be able to gratify ourselves and our readers on this head.

The *Times* Woolwich correspondent (who is not averse to marvels) writes:—"A most wonderful long-range cannon, invented by Mr. Jeffries, patentee of the well-known marine glue, is in course of being mounted in the Royal Arsenal, Woolwich, for experiments at Shoeburyness. Its range or flight of shot is spoken of as certain to eclipse every other weapon hitherto known. The gun, with its present bore—namely, a three-inch diameter—weighs seven

tons, and presents an appearance (with the exception of the present calibre) similar to one of our 68-pounders. The charge will consist of 18 lb. of powder, and a conically-shaped shot, weighted with lead to 9 lb., and hollowed, similarly to the Minié bullet, which it is presumed will be propelled 15 or 20 miles. Mr. Jeffries, it is stated, has asserted his conviction that it would carry from Dover to Calais. It is the intention of the authorities to carry out a varied and complicated course of experiments under the inspection of the Select Committee of Woolwich Arsenal. After being satisfied of its power in its present form, the bore will be progressively increased to a 68-pounder. To enable the gunners to point the gun, the trunnions will be fitted with a couple of telescopes, to assist the eye over the enormous range predicted."

A very curious atmospheric phenomenon is said to have been produced on Friday morning on the railway wires round Paris. "At 7 o'clock, when the service commences in the various stations, it was remarked at the central station, placed at the hotel of the Minister of the Interior, that some of the instruments were charged with electricity, as if the corresponding station had sent a constant current. It was soon found that the fact was general, the wires at all the stations being in the same state. By interrupting the circuit of the wires strong sparks were obtained. The same thing was produced at the same time on all the telegraphic wires throughout France, the stations placed between two lines receiving the current from each side. At half-past nine the electricity, in place of being permanent, showed itself only at intervals. The scientific authorities were consulted as to the cause of this phenomenon. In stormy weather atmospheric electricity produces many discharges, which set in motion the telegraphic machines, but these discharges are instantaneous, and have not a permanent character." So the paragraph runs.

The production of solid bricks has of late received much of the attention of engineers and architects, with a view of their being produced more economically, of a better quality, and with greater facility, than by the time-honoured means known as "hand-moulding;" and although many mechanical contrivances for making bricks have been introduced, not one has realised the requirement practically, or been considered worthy of adoption, until Mr. Henry Clayton, of the Atlas Works, London, produced and patented his brickmaking machine. Its simple and effective character has lately attracted the notice of the able engineer of the South Eastern Railway Company, the directors of which have now had erected a set of Clayton's patent brickmaking machinery on their premises adjoining the railway station at Folkestone for the manufacture of bricks for the use of the company. On an average 20,000 to 25,000 good bricks are made daily by each of Clayton's large machines, with the attention of two men and four boys.

The following is extracted from the foreign correspondence of the *Star*:—"M. Jobard, of Brussels, who has almost suffered himself to be forgotten, from the lengthened and unusual silence he has maintained for some time past, has come out again as enthusiastic and vivacious as ever with his invention of artificial statuary marble—not the veiny, greasy stuff in use for chimneys and vases, but the pure and spotless Carrara, transparent, polished, and hard as the real substance taken from the quarry. This marble, which is to be prepared for the sculptors in a liquid state, will, like many other artificial inventions, possess an immense advantage over the natural production itself. It can be moulded on the plaster figure, and thus instead of having to hack and hew a shapeless block with great pains and labour, the artist will henceforth realise the genuine impression of his cast at once, and, with scarcely any further exertion, bring out his creation with all the freshness and vigour of the first idea. The invention, which has created an immense sensation in the world of art, is due to a practical chemist of Brussels, of the name of Changy, the same skilful practitioner who discovered the divisibility of the electric light, and the miraculous draught of fishes by means of the chemical light which is sunk at the bottom of the sea. M. Jobard, whose word cannot be doubted, pledges his honour that the table on which he writes has been composed by M. Changy's process, and possesses every quality of the finest marble—and that, after having submitted various specimens of the substance, both black and white, to every chemical test in use, he has come to the conclusion that the composition of marble is no longer a secret of Dame Nature, and that man has at length learnt to rival her in the most cunning of her works, while Art will rejoice at beholding her sons freed from the laborious toil which has hitherto rendered the sculptor's profession so difficult of pursuit."

NOTICES.

A correspondent asks the title of a work giving in a tabular form the strength of wires of various gauges and weights. Can any of our readers oblige us with this information?

THE MECHANICS' MAGAZINE will be sent free by post to all subscribers of £1 1s. 8d., annually, payable in advance. Post Office Orders to be made payable to R. A. Brooman, at the Post Office, Fleet Street, London, E.C.

TO ADVERTISERS.

All Advertisements occupying less than half-a-column are charged at the rate of 5d. per line for any number of insertions less than 13; for 13 insertions, 4d. per line; and for 52 insertions, 3d. per line.

Each line consists of 10 words, the first line counting as two. Wood-cuts are charged at the same rate as type for the space occupied.

Special Arrangements for larger or Serial Advertisements. To ensure insertion, Advertisements must reach the Office by 5 o'clock on Thursday evening each week. None can be received after that time for the ensuing number.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

The abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce facts without acknowledgement:—

STEAM ENGINES, &c., 213, 299, 309, 312.
MACHINES AND THEIR FURNACES, &c., 260, 261, 282, 284.
ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 219, 220, 239, 257, 261, 307.
SHIPS AND BOATS, including their fittings, 218, 237, 218, 274, 275.
CULTIVATION OF THE SOIL, including agricultural and horticultural implements and machines, 216, 221.
FOOD AND DRINKS, including apparatus for preparing food for men and animals, 210, 241, 244, 251, 306.
FIBROUS FABRICS, including machinery for treating fibres, paper, paper, &c., 214, 223, 226, 246, 249, 250, 252, 254, 255, 271, 280, 283, 304, 305.
BUILDINGS AND BUILDING MATERIALS, including sewers, chimneys, brick and tile machines, &c., 253, 282, 297.
LIGHTING, HEATING, AND VENTILATING, 232, 266, 268, 277, 281.
FURNITURE AND APPAREL, including household utensils, jewellers, jewellers, musical instruments, &c., 229, 244, 258, 264, 287, 288, 302, 304, 308.
MACHINES, including apparatus for their manufacture, 217, 244, 270, 279, 292.
CHEMISTRY AND PHOTOGRAPHY, 224, 253, 293.
ELECTRICAL APPARATUS, 228, 263.
WEAVING, 236, 242, 259, 275, 286, 300.
LITHOGRAPHY, 271.
MACHINES, 215, 223, 227, 230, 233, 238, 243, 245, 247, 258, 265, 267, 271, 272, 276, 283, 290, 291, 294, 295, 296, 301, 309, 311, 313, 314.

213. J. LAURENCEAU. "Improvements in air-engines." Dated Jan. 24, 1859.

This consists in arrangements of machinery for producing the alternate expansion and contraction of air, and in causing the stroke of a piston to be effected by the expanded air, while the return is effected by the pressure of the atmosphere aided by a partial vacuum obtained at the back of the piston. *Patent completed.*

214. J. and W. H. SMITH. "Certain improvements in manufacturing paper, and in producing water-marks, patterns, figures, letters, and devices thereon, and in the construction of the mechanism employed therein." Dated Jan. 24, 1859.

This invention is not described apart from the drawings. *Patent completed.*

215. J. SAVORY and W. R. BARKER. "Improvements in bottles for medicines and poisons." Dated Jan. 24, 1859.

These bottles are formed with six, eight, or more sides, and are sluted vertically, horizontally, or diagonally. The neck of the bottle is formed so that the liquid will flow but slowly or in drops. *Patent completed.*

216. J. FOWLER, jun., R. BURTON, D. GREIG, and J. HEAV. "Improvements in agricultural implements, and in apparatus used for hauling agricultural implements by steam power." Dated Jan. 24, 1859.

Here the patentees employ a wire-rope and a winding drum so constructed as to hold the rope firmly, and draw the implement steadily forward, notwithstanding that the rope only passes partially round the drum. *Patent completed.*

217. A. WARREN and W. TOTH. "Improvements in the manufacture of iron, and gases for such and other uses." Dated Jan. 24, 1859.

Here in the manufacture of iron in blast and cupola furnaces jets of liquid hydro-carbons are forced in by forcing pumps or apparatus, or by the pressure of a column. The invention also consists in forcing in jets or streams of hydrogen gas into puddling furnaces. To manufacture hydrogen gas a combination of apparatus is employed, consisting of a generator, an instrument to drop water into the generator, and a receiver of the hydrogen gas as it is produced. *Patent completed.*

218. J. G. PROGER and D. DAVIES. "Improvements in lanterns used on board ship to signal to the steersman." Dated Jan. 24, 1859.

A lantern has a single lens turned towards the steersman; it is lighted up at night, and has its cover replaced by a plate of glass in the day. It has also a green and a red glass, the one indicating port, the other starboard. By showing either of these wholly or partially, the steersman is instructed how to put his helm. *Patent completed.*

219. EARL OF CAITHNESS. "Improvements in parts of the permanent way of railways." Dated Jan. 24, 1859.

This consists in making a portion of one or both of the rails at the joints or change of line slide along inclined parallel slots, the two ends of such sliding rails and the ends of the stationary abutting rails being inclined or bevelled to correspond to the incline or bevel of the slots, whereby an overlap bevil joint is obtained. *Patent abandoned.*

220. M. SWAN. "Improvements in ballasting ships, applicable also to the extinguishing fires on board ships." Dated Jan. 24, 1859.

This invention, so far as it relates to the ballasting of ships, consists in constructing the ship with double sides and bottom, that is to say, with an entire inner shell, leaving an air-tight space for water and air at the bottom and sides thereof, forming the ballast chamber or chambers. A semi-circular or other shaped compartment may be made longitudinally over the keel along the bottom of the inner shell, such compartment, which may be sub-divided into a series, being open on its under side so as to receive water from below, and thus form another ballast chamber or set of chambers whilst it adds strength to the ship. This compartment is in direct communication with a valve which admits water through the ship's bottom up to any desired height in the sides, according to the amount of the ballast required, and is also in connection by pipes passing up the inner sides of the ship with the ship's pump. *Patent abandoned.*

221. W. TASKER, jun. "Improvements in ploughs." Dated Jan. 24, 1859.

This relates to fixed headed ploughs, and consists in a construction and arrangement of the parts in connection with the front end of the beam and head gear, whereby the plough may be turned at the headlands without having to be carried round by the ploughman. *Patent completed.*

222. H. OWEN. "Improvements in stockings." Dated Jan. 24, 1859.

This consists in constructing hose, half-hose, &c., with seams or selvage courses about the foot, so that the worn parts may be removed and replaced by new pieces made for the purpose, whereby no overlapping in the seams is required. *Patent completed.*

223. J. H. JOHNSON. "Improvements in machinery or apparatus for cutting and shaping wood." (A communication.) Dated Jan. 25, 1859.

This more especially relates to turning masts and tapered spars, but is applicable to other purposes. The stick of timber is held stationary, being rigidly fixed in the machine, whilst cutters supported in a carriage traverse from end to end of the machine, the cutters revolving at the same time round the stick. *Patent completed.*

224. R. BODMER. "Improved resin and resinous substances." (A communication.) Dated Jan. 25, 1859.

This relates to a former patent dated 27th April, 1858. To get rid of the colour the inventor reduces the temperature at an earlier stage of the process. This modification consists in the addition of a jacket or case to the issue pipe, and the arrangement in connection of apparatus furnishing therewith a constant supply of water or other refrigeratory medium. *Patent completed.*

225. W. CUTTS. "Improvements in the manufacture of bobbins, spools, and cop tubes, and in the machinery employed therein." Dated Jan. 25, 1859.

This consists in manufacturing such articles of paper pulp or other such plastic substance capable of being pressed into the form required. The paper pulp, &c., is run into apertures and compressed by punches. *Patent abandoned.*

226. W. and H. HONGSON. "Improvements in

machinery or apparatus for preparing and spinning wool and other fibrous substances." L. 11112 1859.

This consists in the use of an endless belt of leather forming a continuous travelling surface for supporting and conducting the fibrous substances from the drawing rollers to the guides of the bobbins. *Patent abandoned.*

227. J. WHITE. "Improvements in means or apparatus to facilitate respiration under water, or under the influence of fire, or in other situations where an artificial supply of air may be required, part of which improvements is also adapted to facilitate movements in or upon the surface of water." Dated Jan. 25, 1859.

Here the patentee provides a close covering for the mouth and nose, and also a water and air or a fire-proof covering for the whole body. In connection with this covering to the nose and mouth there are two pipes each provided with a valve, one with an inlet valve for the supply of fresh air, the other with an outlet valve. The pipe for inhaling fresh air may be in connection with a reservoir, or it may be extended above the surface of the water in free communication with the atmosphere. *Patent completed.*

228. W. ANDREWS. "Improvements in electric telegraphs." Dated Jan. 25, 1859.

This consists in arrangements for preventing the return or induced current from interfering with the proper action of the relay instrument. *Patent abandoned.*

229. F. J. JONES. "An improvement in shirt fronts." Dated Jan. 25, 1859.

This applies to those shirt fronts known as "Dickeys," and consists in a new arrangement of neck-band and collar, which also affords the means of securing the false front on the neck of the wearer. *Patent abandoned.*

230. H. BRECKENELL and J. DYER. "Improvements in cocks and valves." Dated Jan. 25, 1859.

Here the passage of the cock or valve is closed by a vulcanized india-rubber washer or disc, having an annular lip or projection moulded thereon, which lip or projection forms the actual contact surface of the washer when the cock or valve is closed. *Patent completed.*

231. I. WOODCOCK. "Improvements in barometer and thermometer dials." Dated Jan. 25, 1859.

This consists in forming those dials of enamelled paper, card-board, &c. *Patent abandoned.*

232. B. SPENDING. "Improvements in apparatus for generating and regulating gas, and for impregnating the same with volatile hydro-carbon fluids." Dated Jan. 25, 1859.

The patentee claims, 1. the moveable syphon, or the principle of bringing the oily matter in contact with different parts of the interior of the retort. 2. The lid, moveable in a groove filled with molten lead. 3. The form of retort by which the chimney passes through its centre with an oval or conical bottom. 4. The application of a regulator and apparatus for further impregnating the gas with the vapour of hydro-carbon fluids. 5. The mode of making the diaphragm, together with general arrangement of parts. *Patent abandoned.*

233. C. G. KELVEY and W. HOLLAND. "An improved escapement for chronometers and other time-keepers." Dated Jan. 25, 1859.

According to the specification of a former patent (dated Oct. 17, 1857,) the inventors apply two rollers to the balance staff. Instead of these two rollers they now employ but one, so that when the proper relative positions of the impulse pallet and the ruby or gold pin are once obtained, no readjustment of the parts will be required. *Patent abandoned.*

234. W. E. NEWTON. "An improvement in life-preserving vests." (A communication.) Dated Jan. 25, 1859.

This relates to vests for ordinary wear, but which are furnished with a float of india-rubber, &c., that can be inflated at pleasure in a few moments without the removal of the vest from the person. *Patent completed.*

235. W. R. ALEXANDER. "Improvements in furnaces, and apparatus for the manufacture of sugar, and for the consumption or prevention of smoke." Dated Jan. 27, 1859.

This consists in effecting the perfect combustion of the fuel, and preventing the discharge of smoke, by an efficient supply of highly-heated air, subdivided into numerous minute jets. *Patent completed.*

236. I. HAXMOND. "Improvements in breech-loading fire-arms, and in cartridges to be used therewith." Dated Jan. 27, 1859.

This invention is not described apart from the drawings. *Patent completed.*

237. O. HUSSEY. "Improvements in the construction of ships' blocks." Dated Jan. 27, 1859.

This consists in fitting the frame with a strap, which allows the sheaves with the frame in which they are mounted to slide a distance within it. A spring of india-rubber is used to keep the frame with the sheaves when the strain is small at the extremity of the strap, but when a sudden jerk comes on the block the spring yields and allows the frame and sheaves to approach for the moment the other end of the strap. *Patent completed.*

238. D. GRAHAM. "An improved method of driving centrifugal machines." (A communication.) Dated Jan. 27, 1859.

This consists in making the vertical shaft that supports the centrifugal hollow at the lower end, with one or more horizontal arms or jets, and connected by pipes and a regulating cock with a vessel or head of water, in which a sufficient pressure of water is maintained to bear the weight of the shaft and drum, with its charge of sugar, &c., to be operated upon. The water will issue from the jets with a force due to the pressure required to buoy up the machine, and make it revolve at any required velocity, the velocity being regulated by the distance of the jets from the centre, and by the size of the orifices. *Patent completed.*

239. J. WELLS and W. CLOUGH. "An improved coupling for railway carriages and analogous uses." Dated Jan. 27, 1859.

Here the carriages are provided with a link at one end and a crook at the other. The noses or hooked ends of the crooks are formed with an incline, so that the link will slide up the incline, and will then drop over the hook on to the bar of the crook. *Patent abandoned.*

240. F. C. C. PAULSEN and A. ALSING. "Improvements in preparing beverages usually called punch." Dated Jan. 27, 1859.

This consists in certain methods of, and in the combination of various ingredients for, the preparation of champagne punch, pine apple punch, arrack punch, and rum punch, which we cannot refer to in detail. *Patent completed.*

241. M. FERNANDEZ. "Improvements in straw and hay cutters." Dated Jan. 27, 1859.

This invention is not fully described apart from the drawings. *Patent abandoned.*

242. J. KERR. "Improvements in the construction of revolving fire-arms." Dated Jan. 27, 1859.

This relates, 1, to those parts of repeating fire arms used for securing the barrel and frame to the stock; 2, to the means of imparting rotary motion to the chamber of repeating fire-arms. There are several detailed arrangements described for carrying the invention into effect for which we cannot give space. *Patent completed.*

243. J. MERCER. "Improvements in the process of currying leather." (A communication.) Dated Jan. 27, 1859.

Here the inventor takes the hides direct from the tan vat or pit, and places them in a machine (similar say to a cotton or cider press) and subjects them to a pressure sufficient to expel the moisture or liquor. He then takes the hides and applies stuffing or grease to them, so that they will be plumped up and made to receive the grease to advantage. *Patent abandoned.*

244. W. AGER. "Improvements in machinery for cleaning rice." Dated Jan. 27, 1859.

This consists in forcing cool air through the body of the rice during the cleaning operation of removing the inner pellicle in order to prevent its heating. *Patent abandoned.*

245. T. HARTSHORNE. "An improved metal to be used for making journey brasses for mills, rollers, forges, and all kinds of shafts and machinery, and also for shipping, and for bearings for shafts and journey brasses in general." Dated Jan. 27, 1859.

This metal will be composed of iron, copper, tin, and reckelous (or regulons) of antimony. *Patent completed.*

246. E. DIXON and H. WHITTAKER. "Improvements in apparatus used in weaving textile fabrics." Dated Jan. 27, 1859.

This consists in an arrangement of self-acting mechanism to be applied to the ordinary shuttles employed in weaving textile fabrics, whereby the stoppage of the loom will be accomplished by the breaking of the weft thread whenever a float or imperfect shed occurs. *Patent completed.*

247. J. MEACHAM. "Improvements in pens and penholders." Dated Jan. 27, 1859.

The object here is to give the writer two pens on one holder. *Patent abandoned.*

248. H. D. P. CUNNINGHAM. "An improvement in the rig of ships or vessels." Dated Jan. 27, 1859.

This consists in a kind of rig which the inventor designates "Double gaff rig," the object being to enable a ship to lie nearer the wind than with sails as ordinarily arranged. *Patent abandoned.*

249. H. RAWSON. "Improvements in machinery

for preparing wool and other fibrous substances." Dated January 27, 1859.

Here the fibre is first conducted between a pair of feeding rollers which carry it forward at a uniform speed; after passing the feeding rollers, the fibres enter amongst teeth which travel with it. These motions cause the teeth first to enter the fibre, then to travel away from the feeding rollers, and afterwards to pass out of the fibre. The patentee prefers to actuate the teeth by a screw gill. In front of the travelling teeth is a plate or frame having a vibratory motion imparted to it in a direction to and from the travelling teeth, and such plate or frame has openings through it for the passage of the teeth of a comb. This comb travels with the plate or frame, and each time that the latter moves from the travelling teeth, the teeth of the comb are projected up through it into the fibre. *Patent completed.*

250. J. BUCKINGHAM and G. SALT. "Improvements in the construction and adaptation of drawing and other rollers employed in drawing and compressing fibres, which improved construction of rollers is also applicable in compressing fabrics." Dated Jan. 27, 1859.
